Effect of verapamil and sodium cromoglycate on leukotriene \( \text{D}_4 \) induced bronchoconstriction in patients with asthma

J A ROBERTS, I W RODGER, N C THOMSON

From the Department of Respiratory Medicine, Western Infirmary, Glasgow

ABSTRACT Leukotriene \( \text{D}_4 \) (LTD\(_4\)) may be an important mediator in asthma. The effect of verapamil and sodium cromoglycate on LTD\(_4\) induced bronchoconstriction has been examined in seven patients with asthma. The bronchoconstrictor response to increasing concentrations of inhaled LTD\(_4\) (0.0032–50 \( \mu \)g/ml) was assessed by measuring changes in FEV\(_1\), specific airways conductance, and flow rate at 30% of vital capacity (\( \dot{V}_{30(p)} \)). Results were expressed as the provocation concentration (PC) producing a 10% fall in FEV\(_1\) (PC\(_{10}\)FEV\(_1\)), a 35% fall in specific airways conductance (PC\(_{35}\)sGaw), and a 30% fall in flow at 30% of vital capacity (PC\(_{30}\) \( \dot{V}_{30(p)} \)). Neither verapamil nor cromoglycate inhibited LTD\(_4\) induced bronchoconstriction in asthmatic subjects. These results suggest that in asthmatic patients LTD\(_4\) induced bronchoconstriction is not mediated via verapamil or cromoglycate sensitive mechanisms.

The leukotrienes (LTs), including LTD\(_4\), may be important mediators in asthma. LTD\(_4\) is released both in vitro and in vivo after allergen challenge, and is a potent bronchoconstrictor. The mechanism of LTD\(_4\) induced bronchospasm in asthma has not, however, been established. The calcium channel blocker verapamil partially inhibits the bronchoconstrictor response to LTD\(_4\) in vivo but not in vitro in non-asthmatic human bronchi, and only at very high concentrations in isolated trachea from the guinea pig. These results suggest that in guinea pigs and non-asthmatic human subjects LTD\(_4\) induced bronchoconstriction occurs as a result both of a direct effect on airway smooth muscle that is insensitive to the inhibitory action of verapamil and of an indirect effect via a verapamil sensitive mechanism. Similarly, in guinea pigs sodium cromoglycate partially inhibits the contractile response to LTD\(_4\) in vivo but not in vitro. Thus in this species cromoglycate appears capable of inhibiting an indirectly mediated bronchoconstrictor response of LTD\(_4\).

In this study we examined the effect of pretreatment with verapamil and sodium cromoglycate on LTD\(_4\) induced bronchoconstriction to determine whether in asthma LTD\(_4\) induced airway narrowing depends on a mechanism sensitive to verapamil or to sodium cromoglycate or on both types of mechanism.

Methods

Patients
We studied seven patients with asthma (table 1), four of whom were women. Their ages ranged from 22 to 49 years. All were atopic and were non-smokers. All were taking inhaled \( \beta_2 \) adrenoceptor agonists by pressurised aerosol, three were taking inhaled corticosteroids regularly, and two were taking sodium cromoglycate. All \( \beta_2 \) agonists were discontinued 12 hours before testing and sodium cromoglycate 24 hours before testing. Inhaled corticosteroids were continued. All subjects gave informed consent and the experimental protocol was approved by the Western Infirmary ethical committee.

In vivo measurements
Airways resistance (Raw) and thoracic gas volume (TGV) were measured in a constant volume body plethysmograph (Fenyves and Gut), a computerised data collection and analysis system based on the method of DuBois et al being used. The results were expressed as specific airways conductance (sGaw) \((= 1/\text{Raw} \times \text{TGV})\). The mean of eight measurements was taken for the sGaw value. The maximum ex-
piratory flow at 70% of expired vital capacity, obtained from a partial flow-volume (V_{300}) curve, and the forced expiratory volume in one second (FEV₁) were measured automatically (Collingwood Measurement). The flow-volume curves were obtained as follows: after a period of normal tidal breathing, the subject expired maximally from end tidal inspiratory volume to residual volume (RV) to obtain the partial expiratory flow-volume (PEFV) curve. When RV was reached the subject inspired to total lung capacity (TLC) and expired maximally to RV. From this manoeuvre FEV₁ was calculated. Body plethysmographic measurements preceded flow-volume recordings. Aerosols were generated with a Wright nebuliser by air of 50 lb/in² (345 kPa) at a flow rate of 8 l min⁻¹ to achieve an output of 0.15 ml min⁻¹.

### DOSE-RESPONSE CURVES

The study was performed in two parts, which were carried out sequentially two months apart. In the first part (Nos 1–4) patients received either verapamil (2.5 mg/ml) or normal saline in a randomised double blind manner on three separate days (two saline). After baseline measurements of sGaw (mean of seven readings) and V_{300} and FEV₁ (mean of five readings), the solutions were inhaled for five minutes. After 10 minutes lung function tests were repeated and each subject then inhaled increasing concentrations of leukotriene (0.0032–50 μg/ml). Each concentration was inhaled for two minutes and inhalations were repeated every 15 minutes. Results were expressed as the provocation concentration (PC) producing a 35% fall in sGaw (PC_{35}sGaw), a 30% fall in V_{300}(PC_{30}V_{300}), and a 10% fall in FEV₁ (PC_{10}FEV₁).

In the second part of the study patients (Nos 1–4, 6, 7) inhaled either sodium cromoglycate (10 mg/ml) or placebo for five minutes in a randomised double blind manner. Measurements were taken both before and after inhalation of placebo. A dose-response curve for LTD₄ was then constructed as described above. On a separate day a dose-response curve for methacholine was obtained in a single blind manner according to the protocol described by Hargrave et al. The average PC value for the two postsaline LTD₄ dose-response curves was used for the comparison with the results obtained after inhalation of verapamil. Results were compared by means of analysis of variance and Student's t test.

### Results

The PC_{20}FEV₁ for methacholine ranged from 0.17 to 0.64 mg/ml, confirming that these patients had bronchial responsiveness values in the asthmatic range.

Inhalation of verapamil did not alter baseline FEV₁, sGaw, or V_{300} (table 2). All patients developed appreciable bronchoconstriction as assessed by PC₁₀FEV₁, PC_{35}sGaw and PC_{30}V_{300}. Pretreatment with verapamil did not modify this response (fig 1). The geometric mean PC₁₀FEV₁ was 0.35 μg/ml after verapamil compared with 0.47 μg/ml after the control (NS). PC_{35}sGaw was 0.69 μg/ml after control and 0.37 μg/ml after verapamil (NS). Mean PC_{30}V_{300} was 0.41 μg/ml after the control and 0.31 μg/ml after verapamil (NS). Sample dose-response curves for

Effect of verapamil and sodium cromoglycate on leukotriene D\textsubscript{4} induced bronchoconstriction in asthma

Fig 1  Effect of pretreatment with verapamil (2.5 mg/ml) or control (phosphate buffered saline) on airway responsiveness to leukotriene D\textsubscript{4} (LTD\textsubscript{4}). Results are expressed as the provocation concentration (PC) producing a 10\% decrease in FEV\textsubscript{1} (PC\textsubscript{10}FEV\textsubscript{1}), a 35\% decrease in specific airways conductance (sGaw—PC\textsubscript{35}sGaw), and a 30\% fall in the partial flow-volume curve (V\textsubscript{30}(p)—PC\textsubscript{30}V\textsubscript{30}(p)). Mean values of PC\textsubscript{10}FEV\textsubscript{1}, PC\textsubscript{35}sGaw, and PC\textsubscript{30}V\textsubscript{30}(p) are shown as horizontal bars.

Sodium cromoglycate did not significantly alter baseline FEV\textsubscript{1} sGaw or V\textsubscript{30}(p) (table 3) and did not alter responsiveness to LTD\textsubscript{4} (fig 3). The geometric mean PC\textsubscript{10} FEV\textsubscript{1} was 0.22 µg/ml after control and 0.24 µg/ml after sodium cromoglycate (NS). PC\textsubscript{35}sGaw was 0.21 µg/ml after control and 0.19 µg/ml after sodium cromoglycate. PC\textsubscript{30}V\textsubscript{30}(p) was 0.21 µg/ml after control and 0.19 µg/ml after sodium cromoglycate. Sample dose-response curves for sGaw against log concentration LTD\textsubscript{4} (after placebo and cromoglycate) are shown (fig 4). All patients developed chest tightness but none coughed after LTD\textsubscript{4}.

Discussion

These results show that neither the calcium channel blocker verapamil nor sodium cromoglycate modifies LTD₄ induced bronchoconstriction in patients with asthma. In contrast to the finding with verapamil, we recently showed that in non-asthmatic subjects⁶ the calcium channel blocker significantly reduced the constrictor response to LTD₄.

Why should verapamil have a protective effect against LTD₄ induced bronchoconstriction in normal subjects but not in asthmatic patients? It has been suggested that there may be heterogeneity of LTD₄ receptors, and that drugs vary in their ability to block the response to LTD₄ according to the different affinities of their LTD₄ receptors.¹² In support of this hypothesis, the calcium channel blocker diltiazem inhibits the contraction of guinea pig lung parenchymal strips in response to high dose LTD₄ whereas the

![Fig 3](http://thorax.bmj.com/)

Fig 3  Effect of pretreatment with sodium cromoglycate (10 mg/ml) or control (phosphate buffered saline) on airway responsiveness to leukotriene D₄ (LTD₄). Results are expressed in a similar manner to those in figure 1. Sodium cromoglycate did not significantly reduce the response to LTD₄.

Effect of verapamil and sodium cromoglycate on leukotriene \( \Delta_4 \) induced bronchoconstriction in asthma

SRS-A antagonist FPL55712 inhibits only the low dose part of LTD\(_4\) induced contraction.\(^{12}\) Since the non-asthmatic subjects inhaled higher concentrations of LTD\(_4\) than the asthmatic patients,\(^{6}\) this may have meant that the low affinity LTD\(_4\) receptors sensitive to calcium channel blockers were stimulated only in the normal subjects. An argument against this mechanism is that verapamil does not significantly inhibit the contractile response of in vitro preparations of human bronchi to different doses of LTD\(_4\), although a slight non-significant reduction of response to the highest concentration of LTD\(_4\) was observed.\(^{6}\)

An alternative explanation of these findings is that LTD\(_4\) induced bronchoconstriction in asthmatic patients may be due to a direct effect on airway smooth muscle, whereas in non-asthmatic subjects airway narrowing occurs because of a combination of direct action via bronchial smooth muscle receptors and indirect verapamil sensitive mechanisms. This indirect mechanism may have a higher threshold before LTD\(_4\) produces an effect. Possible indirect mechanisms by which LTD\(_4\) might cause bronchoconstriction include reflex vagal bronchoconstriction\(^{7,13}\) and release of secondary mediators.\(^{14}\)

A third possibility is that the action of verapamil is dependent on an intact respiratory epithelium. Recently Raeburn \textit{et al}\(^{15}\) have shown that verapamil inhibits induction of airway smooth muscle contraction by LTD\(_4\) in the rabbit only when the airway mucosa is intact. Since patients with even mild asthma have damaged mucosa,\(^{16}\) the absence of an inhibitory effect of verapamil on LTD\(_4\) induced bronchoconstriction could be due to the lack of an intact mucosa in those with asthma.

If LTD\(_4\) is confirmed as an important mediator in asthma, it could be predicted from our findings that verapamil would not be an effective drug in asthma. The results of most studies using calcium channel blocking drugs in asthma would support this suggestion. Neither verapamil nor nifedipine significantly alter resting bronchomotor tone and they produce little or no protection against bronchoconstriction induced by allergen.\(^{17,18}\) They are moderately effective in inhibiting exercise induced asthma.\(^{19,20}\)

Sodium cromoglycate inhibits mast cell degranulation, but may have other modes of action.\(^{21}\) Its duration of action at concentrations used in our protocol is two to four hours.\(^{22}\) In guinea pigs in vivo sodium cromoglycate partially inhibits LTD\(_4\) induced bronchoconstriction.\(^{7}\) In patients with aspirin induced asthma the response to aspirin challenge can be blocked by sodium cromoglycate.\(^{23}\) The pathogenesis of aspirin induced asthma is unknown but increased production of lipoxygenase products such as LTD\(_4\) may play a part.\(^{24}\) Possibly sodium cromoglycate acts as a leukotriene antagonist. Our results show that sodium cromoglycate is not a specific inhibitor of LTD\(_4\) in patients with asthma. This finding confirms and extends the work of Holroyde \textit{et al}.\(^{6}\) who showed that in normal subjects sodium cromoglycate had no effect on airway narrowing induced by LTD\(_4\).

In summary, we have shown that neither verapamil nor sodium cromoglycate inhibits LTD\(_4\) induced bronchospasm in patients with asthma. This contrasts with the action of verapamil in non-asthmatic subjects.
