Aeromonas hydrophila fulminant pneumonia in a fit young man

J Rosal Gonçalves, Gabriela Brum, Afonso Fernandes, Isabel Biscaia, Maria José Salvado Correia, Joaquim Bastardo

Abstract
A previously healthy 24 year old athletic man became ill suddenly with pneumonia the day after swimming in the sea. Despite intensive support measures in the intensive care unit he died three hours after admission and 21 hours after his first symptom. Necropsy showed bilateral haemorrhagic necrotising pneumonia. Aeromonas hydrophila was isolated from a blood culture taken at admission and from the lungs at necropsy. The infection may have come from contaminated sea water.

Aeromonas hydrophila is an anaerobic Gram negative bacillus that commonly inhabits soil and fresh water. It has been regarded as an opportunistic agent as most cases of infection have occurred in immunologically compromised hosts. Infections in apparently healthy people have been described recently, however. The range of infections attributed to this microorganism is large but pneumonia has been rare.1-3

We describe fulminating aeromonas hydrophila pneumonia in a previously fit young man.

Case report
A 24 year old man was admitted to the intensive care unit in severe respiratory distress. He had been in good health but became ill suddenly 18 hours before admission with severe right pleuritic chest pain, cough with small haemoptyses, fever, and increasing shortness of breath. He had swum in the sea 24 hours before he became ill. He had no unusual social or epidemiological history.

On admission he was an alert, muscular young man with severe dyspnoea and cyanosis. His temperature was 37·8°C, respiratory rate 35/min, pulse 120 beats/min, and blood pressure 80/40 mm Hg. There were no skin lesions. Clinical and radiographic examination of the chest showed consolidation of the right upper lobe.

The packed cell volume was 0·52, white blood cell count $9·4 \times 10^9/l$, and platelet count $24·5 \times 10^9/l$. He was serum negative for HIV-1 and HIV-2. His arterial oxygen ($P_{aO_2}$) and carbon dioxide ($P_{aCO_2}$) tensions when he was breathing air were 6·7 and 3·6 kPa; the pH was 7·38. Intensive medical support, including assisted ventilation, was begun but his arterial blood gas tensions continued to deteriorate. After two hours of intensive medical aid he coughed up about 15 ml of bright red blood, became severely shocked, and despite intensive medical efforts died three hours after admission.

At necropsy the lungs were heavy, the left lung weighing 790 g and the right 870 g. The right lung was uniformly and diffusely solid and the left lung had multiple confluent foci. Microscopically there was vascular engorgement and the alveoli were flooded with erythrocytes and mononuclear and granular leucocytes. Zones of necrosis and haemorrhage were present. Many small Gram negative bacilli were seen in both lungs, especially in the areas of necrosis. Other organs were normal apart from generalised congestion.

An organism recovered from blood was cultivated on brain-heart infusion at 37°C after 24 hours and one from a necropsy sample of the lung after plating on to blood agar and McConkey agar and overnight incubation at 37°C. It was provisionally identified as Aeromonas sp on the basis of aerobic growth of a Gram negative rod, being oxidase and catalase positive and showed $\beta$ haemolysis of blood agar. Its final identification as A hydrophila was confirmed by the API 20 NE technique (API System), isolates from the two sources having the same biochemical profiles.

Antibiotic sensitivity testing was performed by the comparative disc diffusion method4 on DST agar at 37°C. The organism was resistant to ampicillin, carbenicillin, and cephalothin and sensitive to gentamicin, amikacin, cefuroxime, and co-trimoxazole.

Discussion
Aeromonas hydrophila is an anaerobic Gram negative bacillus found primarily in fresh water and soil habitats. Human infections with this agent are usually due to exposure to contaminated water. Their origin can, however, be endogenous, coming from the intestine. It was initially believed that Aeromonas was basically an opportunistic agent, but infections in apparently healthy people have been described recently, including meningitis,5-7 arthritis,8 and pulmonary9 and hepatic abscess.7 Septicaemia is a frequent complication.

A hydrophila pneumonia is quite rare. Of the 12 published cases,1-3 10 occurred in men. Predisposing factors were found in all but three of the cases. In eight the infection was attributed to near drowning in contaminated water. The acute infection was fatal in five subjects. Nosocomial infections caused by A hydrophila have also been described.1-10 No predisposing factor was identified in our patient, the only relevant factor being his recent swim in the sea. Although A hydrophila is not considered a marine bacterium, it is tolerant to sodium chloride and to tem-
peratures from 4° to 45°C, and is able to survive in sea water. This seems the most probable environmental source for this case.

Laboratories should be altered to the pos-
sibility of A hydrophila as a potential patho-
genic organism. Treatment with amino-
glycosides and vigorous pulmonary and
cardiacoal vascular support is required. Clinicians
should be aware of the virulence of this rare
organism.

Little Old New York

Having long since acquired the trappings of a
backwoodsman, I sometimes contemmate with
pleasure 1938. That was the year in which, aged
28 and fresh from a general medical registrar-
ship, I sailed to New York with a view to
furthering my knowledge of chest medicine.

In good fortune, I was introduced to two of the
most distinguished members of our specialty—

namely, Dr Eugene Opie, professor of
pathology at New York Hospital, and Professor
J Burns Amberson of Bellevue Hospital,
perhaps the best known chest physician at that

time.

Reporting to Dr Opie, I was soon immersed
in controversies over natural and acquired
immunity and resistance to tuberculosis in
various animal species, a subject on which a
dozen or so doctors were working in his depart-
ment. I was set the task of tracing the fate of
tubercle bacilli after their intravenous injection
into rats. I will never forget the occasion when a
laboratory assistant called Mr Lardy dumped a
large toffee tin on my bench containing 20-30
albino rats each weighing about 150 grams.

With his aid in anaesthetising and holding
them down, I made a nick in the groin and
injected a measured dose of bacilli into the saphenous (or was it the femoral?) vein. To this
day I believe that the veins were smaller than
the needles I was required to insert, but with
practice I became proficient. These and other
tins of rats were killed at intervals from half an
hour to six months and the numbers of bacilli in
their lungs and elsewhere were counted. With
the aid of Dr Opie, an article eventually
appeared in the Archives of Pathology.

Soon after my arrival I was shown some
radiographs of the chest of macacus thsus
monkeys with massive tuberculous hilar lymph
nodes. Having commented that the films were
all overexposed, I was delegated to radiograph
up to 20 of them twice a week. In time, I learnt
the technique of extracting them from their
cages without being nipped and then carrying
them, one in each hand with their arms behind
their backs, to the obsolescent x ray machine.

With the monkeys breathing at 50-60 times a
minute in short bursts and the machine needing
an exposure of at least half a second, good
timing was essential. I think I convinced the
pathologists who had infected the monkeys that
my films were an improvement.

Three times a week I had the privilege of
joining the small group accompanying Dr
Amberson on his ward rounds. It was an
unforgettable experience. Quite apart from the
clinical aspect, there was the sight of a busy
city hospital with beds down the centre of the
wards and along the corridors and much coming
and going. After a particularly noisy distribution
of newspapers during one round, Dr Amberson
pointed out that the paperman possessed a
quality that Sir William Osler insisted all good
physicians should possess—namely, impertur-
bability. It seemed to me to be a desirable
quality in anyone wishing to survive the hub-
bub of Bellevue and one that Dr Amberson
possessed in good measure.

Some years later, on my next visit to New
York, I called on Dr Opie and said I felt a little
guilty that he had made possible such a splen-
did year and I had given so little in return. He
pointed out that he had always welcomed
postgraduates who were properly recommen-
ded, that his assistants covered a wide range of
seniority, and that he tried to ensure that each
one was given a task appropriate to his ability.

Is it fair for a clinician to burst into a scientific
department and stay for only a year? Dr Opie
seemed to think that it was. Maybe I provided a
useful pair of hands in his overall study of
immunity in tuberculosis and at the same
time used my research fellowship profitably.
Whatever the answer may be, the experience I
acquired in scientific methods in what was then
affectionately called Little Old New York
profoundly influenced my approach to clinical
medicine.—NEVILLE C OSWALD
