Persistent alveolar increased permeability to 
99mTc DTPA in patients with advanced HIV infection
In their paper regarding the diagnostic value of lung clearance of 
99mTc DTPA in 
Pneumocystis carinii pneumonia Dr D S Robinson and his colleagues (October 1991;46:722-6) emphasised the specificity of the shape of the clearance curve by noting that none of their patients who did not have pneumocystis pneumonia had a biphasic curve in both the upper and the lower zones of the lung.
We have observed three HIV infected homosexual men who died of 
Pneumocystis carinii pneumonia in whom 
99mTc DTPA transfer time (mean (SE) T99m) ranged from 3.1 to 4.6 (mean 4.3) minutes and was biphasic in the upper, mid and lower zones after a follow up period of four, 18, and 31 weeks. This compares with a mean 
99mTc DTPA transfer time in five HIV patients with pneumocystis pneumonia of 3.1 (1.4) (range 1.8-9.6) minutes with no significantly lower than transfer times in HIV positive patients with various non-pneumocystis pneumonia chest condi-
