Nasal provocation with AMP

We read with interest the article on histamine release following nasal provocation with adenosine 5'-monophosphate (AMP). In contrast to the recently published in Respir Crit Care Med article on histamine release following nasal provocation with AMP, we have demonstrated a wide variation in AMP-induced histamine release from BAL fluid mast cells in 37 out of 54 consecutive samples of BAL fluid from 37 out of 54 patients attending hospital for routine bronchoscopy, adenosine alone caused histamine release (maximum 20.6 (2.5)% of the total cellular content of the amine). The adenosine receptor agonists R-PIA, NECA, and CGS21680 also induced histamine release from BAL fluid mast cells. Preincubation of BAL fluid mast cells with the adenosine receptor antagonist xamime congener caused significant inhibition of the response to adenosine (p = 0.007).

Our findings indicate a means by which adenosine challenge of the airways can induce bronchocostriction and support a role for adenosine in the pathophysiology of asthma. The results suggest that cells obtained from BAL fluid may provide the ideal model for the testing of novel, adenosine receptor, targeted therapies for asthma. The interindividual variability in response to adenosine and adenosine agonists is therefore most probably due to the variation in the clinical histories of this unselected population. Previously we have found a wide variation in response to substance P in such unselected patients, although the variation in response was not present in further studies in a clearly defined asthmatic population.

We are currently investigating the action of adenosine on BAL fluid cells employing carefully defined subject groups of atopic asthmatic subjects, atopic non-asthmatic subjects, and non-atopic non-asthmatic controls.

AUTHOR’S REPLY

That airway responsiveness to nebulised adenosine is a more selective indicator of allergic inflammation than other non-specific stimuli such as histamine or methacholine is supported by a number of clinical studies.1 Although activation of neural pathways2 and the intrinsic hyperresponsiveness of the bronchal smooth muscle to adenosine may contribute to adenosine-induced bronchoconstriction in asthma, enhanced mast cell releasability in vivo is a primary determinant for these responses.

We are glad to learn that, in keeping with our previous findings in the lower3 and upper airways,4 Ennis et al have recently shown that adenosine elicits a significant histamine release from BAL fluid mast cells in 37 out of 54 consecutive samples of BAL fluid from 37 out of 54 patients attending hospital for routine bronchoscopy.1 It would be of interest to know whether adenosine potentiates histamine releasability in those BAL fluid mast cells obtained from atopic individuals and to investigate whether PCP, which is adenosine, correlates with the extent of mast cell releasability. This would further substantiate the view of adenosine bronchial provocation as a potential new marker of airway inflammation in asthma.

Interestingly, Ennis et al provide evidence for an A2A-mediated mechanism for the adenosine induced histamine release from BAL fluid mast cells (since CGS21680 is a selective A2A agonist whereas A1 receptors are mainly indicated to be involved in the activation of human mast cells). This needs to be carefully investigated as the appreciation of the potential role of A2A receptors in mediating adenosine induced responses in human mast cells raises the possibility that these receptors could become the target for future drug development.

20th International Symposium on Intensive Care and Emergency Medicine

The 20th International Symposium on Intensive Care and Emergency Medicine will be held on 21–24 March 2000 at the Congress Center in Brussels, Belgium. For further information contact Carl Vanhaesendonck, Telephone: 322 555 3215/3631, Fax: 322 555 4555, email: sympicu@ulb.ac.be.

BOOK REVIEW

Key Topics in Respiratory Medicine.

This book from the Key Topic Series is aimed at postgraduate students in medicine (those sitting MRCP examinations and other trainees (including intensivists and anaesthetists) who come into contact with respiratory medicine during their clinical practice. It is divided into discrete, although overlapping, topics in a standard format covering respiratory symptoms, pathologies and clinical scenarios.

The schematic radiograph on the front cover belies the conspicuous absence of pictures, diagrams or radiographs throughout the rest of the book. It is particularly remarkable that the chapters on chest x rays and diagnostic imaging are thus unfurnished. Similarly, lung function tests are explained with great clarity and serve as a useful revision tool, but without the assistance of any diagrams their value to the novice is limited. The chapters on Astynergis, diffuse parenchymal lung disease and pneumoconiosis were, however, very helpful in clarifying what can be confusing nomenclature. The common respiratory problems (particularly asthma, chronic obstructive pulmonary disease (COPD), lung cancer, and pneumoconiosis) are all covered excellently with clear, up to date overviews. Their management sections are well supported by reference to the British Thoracic Society guidelines which enhances the usefulness of the book in clinical practice. Other chapters which deal with respiratory disease in special situations add to the interest and breadth of the text.

I would reiterate the recommendation of the book as a useful text in preparation for both the written and clinical sections of the second part of the MRCP examination. It admirably fulfils its intentions by providing a concise, exceptionally factual, account of clinical respiratory medicine, despite the conspicuous absence of illustrations.—SS
