Association of IL-1β and IL-1 receptor antagonist haplotypes with rate of decline in lung function in smokers

Abstract

Background—There is increasing evidence that the cytokine network is central to the immunopathology of inflammatory airway diseases. The interleukin 1 (IL-1) receptor antagonist (IL-1RN) is a naturally occurring anti-inflammatory agent that binds to the IL-1 receptor but does not possess agonist activity. Each of the genes of the IL-1 locus on chromosome 2q14 is polymorphic. The *IL1B* gene contains an 86 bp tandem repeat and allele 2 of this polymorphism has been associated with various inflammatory diseases. The IL-1β (*IL1B*) gene contains a promoter polymorphism (C–511T) that has been associated with inflammatory diseases and is in linkage disequilibrium with the *IL1RN* polymorphism.

Methods—We investigated whether polymorphisms in the *IL1B* and *IL1RN* genes were associated with rate of decline in lung function. Genotypes were determined in 284 smokers with a rapid decline in lung function and 306 smokers with no decline in lung function.

Results—None of the genotypes was associated with the rate of decline of lung function. However, the distribution of *IL1B*/*IL1RN* haplotypes was different between smokers with a rapid decline in lung function and those with no decline in lung function (*p* = 0.0005).

Conclusion—These results suggest that *IL1B*/*IL1RN* haplotypes play a role in the rate of decline in lung function in smokers.

Keywords: interleukin 1; lung function; smoking; polymorphism (genetics)

Interleukin 1 (IL-1) and similar cytokines play a central role in chronic inflammatory diseases. The IL-1 family consists of two pro-inflammatory cytokines, IL-1α and IL-1β, and a naturally occurring anti-inflammatory agent, the IL-1 receptor antagonist (IL-1RN). The two forms of IL-1 are the products of different genes, but they are structurally related and bind to the same receptor. They are synthesised by a variety of cell types, mainly monocytes and macrophages. IL-1RN is a 16–18 kD protein that binds to the IL-1 receptor with the same affinity as IL-1 but does not possess agonist activity and therefore acts as a competitive inhibitor of IL-1. IL-1 and its antagonist may influence the rate of decline in lung function because of the effects of IL-1 on neutrophil function and chemotaxis. IL-1 stimulates the synthesis of IL-8 which is a potent chemotactic agent for neutrophils and it also induces release of neutrophil elastase. IL-1 promotes the adhesion of neutrophils and other cells by enhancing the expression of adhesion molecules such as ICAM-1, VCAM-1, and l-selectin.

Evidence for a contribution of the IL-1 gene complex to the pathogenesis of inflammatory airway disease was provided by measurements of IL-1 in asthmatic subjects. IL-1β expression in the alveolar macrophages of asthmatic subjects is upregulated and there is increased protein expression of both IL-1β and IL-1RN in biopsy specimens of the bronchial epithelium of asthmatics. In animal models, intratracheal administration of IL-1β to Brown-Norway rats leads to an increased number of neutrophils in bronchoalveolar lavage fluid and increased airway hyperresponsiveness to bradykinin. Pretreatment with IL-1RN reduces bronchial hyperreactivity in guinea pigs.

The genes of the IL-1 complex map to the long arm of chromosome 2, and each of the genes is polymorphic. The IL-1β gene (*IL1B*) has a single nucleotide polymorphism in the promoter region (C–511T) and the *IL1RN* gene has a penta-allelic polymorphic site in intron 2 containing 2–6 tandem repeats of an 86 bp sequence. There is evidence that allele 2 of the *IL1RN* gene (*IL1RN*2) is associated with increased susceptibility or more severe outcome in chronic inflammatory diseases such as ulcerative colitis, systemic lupus erythematosus, and alopecia areata. The *IL1B* C–511T has been associated with inflammatory bowel disease as well as plasma levels of IL-1β and IL-1RN.

Chronic obstructive pulmonary disease (COPD) is a chronic inflammatory disease that is associated with progressive airway remodelling and obstruction. The role of *IL1B* and *IL1RN* polymorphisms in COPD has only been investigated in a small number of subjects. *IL1RN*2 has been associated with non-atopic asthma in a Japanese population, but not in black or white South African individuals. We hypothesised that carriers of *IL1RN*2 and *IL1B* C–511T who smoked would have more severe airflow obstruction and a more rapid decline in lung function than smokers who did not have these alleles.

Methods
SUBJECTS
Subjects were selected from the participants in the NHLBI Lung Health Study. The design of this multicentre randomised clinical trial is described more extensively elsewhere.23 Study participants were healthy current smokers aged 35–60 who had mild to moderate airflow obstruction (forced expiratory volume in 1 second (FEV1) 55–90% of predicted). Exclusion criteria included serious illnesses such as cancer, heart attack, stroke, or other important conditions that required medical treatment. The primary outcome was rate of decline of FEV1 over a follow up period of 5 years. Of the 3216 persistent smokers in this cohort, 284 were chosen for having the most rapid decline in lung function (decline in FEV1 >0.4% predicted per year), and 306 were selected because of absence of decline over the same period (increase in FEV1 >0.4% predicted per year). All participants were white.

STATISTICAL ANALYSIS
The results are presented as genotype and allele frequencies for both subjects with a rapid decline in lung function and those with no decline in lung function among the participants in the Lung Health Study. \( \chi^2 \) tests for statistical significance were performed on allele frequencies. Logistic regression was used to adjust the results for potentially confounding variables such as age, sex, cigarette smoking, baseline lung function, and response to methacholine. Unpaired t tests were used to compare baseline values. Haplotype frequencies and linkage disequilibrium were estimated using the expectation-maximisation (EM) algorithm implemented in the Arlequin software package.15

Results
The characteristics of the 590 smokers are given in table 1. Figure 1A shows the distribution of IL1RN genotypes within the groups of smokers who had a rapid decline and those with no decline in lung function. The observed genotype frequencies were similar to those previously reported.12 Figure 1B shows the distribution of IL1B genotypes in the smokers who had a rapid decline and those who had no

Five alleles of the IL1RN gene have been previously described.12 We found a sixth allele that consisted of eight repeats of the 86 bp sequence (fig 2).

Discussion

We have investigated polymorphisms in the IL-1 gene cluster as risk factors for accelerated decline in lung function. Genotype frequencies were compared in smokers with a rapid decline in lung function and those with no decline in lung function. There was a strong association between IL1RN/IL1B haplotypes and decline in lung function. Allele 1 of the IL1RN gene in combination with the IL1B T allele was a risk factor for an accelerated rate of decline in lung function. In contrast, allele 2 of the IL1RN gene in combination with the IL1B T allele was protective against a rapid decline in lung function.

IL1B and IL1RN are logical candidate genes in inflammatory airway diseases because of the critical role of IL-1 in inflammation. The actions of IL-1 include activation of T and B cells, and chemotaxis of neutrophils and macrophages. In addition, IL-1 stimulates the production of other cytokines such as tumour necrosis factor (TNF) and granulocyte-macrophage colony stimulating factor (GM-CSF). Airway inflammation is a common feature in the development of both COPD and asthma. Previous studies have shown an association between IL1RN*2 and several inflammatory and autoimmune diseases such as ulcerative colitis, systemic lupus erythematosus, diabetic nephropathy, and alopecia areata.13–17 Another polymorphism in the IL1RN gene, which is in complete linkage disequilibrium with IL1RN*2, has been associated with fibrosing alveolitis.27 The IL1B C–511T polymorphism has been associated with several diseases including inflammatory bowel disease,15 alcoholic cirrhosis,28 and Parkinson’s disease.29

The functional effect of these polymorphisms remains unclear. Data on the effect of IL1RN*2 on plasma levels of IL-1RN are contradictory.30–31 Hurme et al investigated the effect of IL1RN*2 in combination with the IL1B C–511T polymorphism and found that IL1RN*2 was associated with higher plasma levels of IL-1RN than IL1RN*1, but only in individuals who also had the T allele of IL1B.19 These data would appear to conflict with the reported association of the IL1RN*2 allele with inflammatory diseases since increased production of IL-1RN would be expected to reduce the binding of IL-1 to its receptor and therefore have an anti-inflammatory effect. However, mononuclear cells from carriers of the IL1RN*2 allele were shown to produce a higher level of IL-1β in vitro.32 It is possible that IL1RN*2 predominantly increases the level of IL-1β and therefore leads to an imbalance in the IL-1β/IL-1RN ratio resulting in an increased susceptibility or more severe outcome of inflammatory diseases. Alternatively, it could be hypothesised that the IL1RN*2 allele is a marker for a linked disease associated locus and may not be a direct disease causing allele.
We found no association of either the IL-1RN or IL-1β genotypes with the rate of decline in lung function. However, the association of haplotypes strongly suggests that the combination of risk alleles contributes to the susceptibility to the deleterious effects of cigarette smoke on lung function. This is consistent with the in vitro data of Hurme et al. IL1RN*2 in the presence of the IL1B T allele was associated with higher levels of IL-1RN in vitro and with a normal rate of decline in lung function in this study. Conversely, IL1RN*1 in combination with the IL1B T allele was associated with lower levels of IL-1RN in vitro and with an accelerated rate of decline in lung function. Individuals with lower levels of IL-1RN may therefore be less protected against the pro-inflammatory effects of IL-1 and thus may be more susceptible to cigarette smoke induced lung injury.

In summary, although the individual polymorphisms in the IL-1 genes were not associated with rate of decline in lung function in smokers, we were able to demonstrate a significant influence of IL1RN/IL1B haplotypes in these individuals. As in previous functional studies, this suggests that it is the combination of alleles which is important in the regulation of IL1RN gene expression.
