Hormone replacement therapy (HRT) as a remedy for menopausal symptoms has long seemed to be biologically plausible, although there has been no firm assessment of its side effects. As a result of the Women’s Health Initiative and other trials, in the last few years there has been an increasing awareness of the risks of HRT, mainly on cardiovascular diseases, stroke, venous thromboembolism, and breast cancer. Less attention has been paid to the effects of HRT on the airways, even though there is mounting—but somewhat contradictory—evidence of an association between HRT and BMI in tertiles were performed.

Background: Hormone replacement therapy (HRT) and obesity both appear to increase the risk of asthma. A study was undertaken to investigate the association of HRT and hay fever in a population of perimenopausal women, focusing on a possible interaction with body mass index (BMI).

METHODS: A postal questionnaire was sent to population based samples in Denmark, Estonia, Iceland, Norway, and Sweden in 1999–2001, and 8588 women aged 25–54 years responded (77%). Pregnant women, women using oral contraceptives, and women <46 years were excluded. Analyses included 2206 women aged 46–54 years of which 884 were menopausal and 540 used HRT. Stratified analyses by BMI in tertiles were performed.

Results: HRT was associated with an increased risk for asthma (OR 1.57 (95% CI 1.07 to 2.30)), wheeze (OR 1.60 (95% CI 1.22 to 2.10)), and hay fever (OR 1.48 (95% CI 1.15 to 1.90)). The associations with asthma and wheeze were significantly stronger among women with BMI in the lower tertile (asthma OR 2.41 (95% CI 1.21 to 4.77); wheeze OR 2.04 (95% CI 1.23 to 3.36)) than in heavier women (asthma: pinteraction = 0.030; wheeze: pinteraction = 0.042). Increasing BMI was associated with more asthma (OR 1.08 (95% CI 1.05 to 1.12) per kg/m²). This effect was only found in women not taking HRT (OR 1.10 (95% CI 1.05 to 1.14) per kg/m²); no such association was detected in HRT users (OR 1.00 (95% CI 0.92 to 1.08) per kg/m²) (pinteraction = 0.046). Menopause was not significantly associated with asthma, wheeze, or hay fever.

Conclusions: In perimenopausal women there is an association between HRT and BMI in the effects on asthma. Lean women who were HRT users had as high a risk for asthma as overweight women not taking HRT. It is suggested that HRT and overweight increase the risk of asthma through partly common pathways.
questionnaire was sent to 3000–4300 subjects in each centre. The population included in the RHINE study consisted of responders from Reykjavik in Iceland, Bergen in Norway, Umeå, Uppsala and Gothenburg in Sweden, Aarhus in Denmark, and Tartu in Estonia (n = 21802, response rate 83.7%). The eligible subjects (excluding 264 deaths) were sent a postal questionnaire in 1999–2001. Subjects not responding to the first mailing were sent two reminders. In total, 16 191 subjects answered the questionnaire including responders from Reykjavik in Iceland, Bergen in Norway, Umeå, Uppsala and Gothenburg in Sweden, Aarhus in Denmark, and Tartu in Estonia (n = 21 802, response rate 85.88 women (response rate 77%) born between 1945 and 1973.

Analyses were restricted to women aged 46–54 years since the mean age of onset of the perimenopausal transition is 45–46 years.24 Pregnant women (n = 6) and women using oral contraceptives (n = 72) were excluded, leaving 2206 women for analyses. There were 121 women younger than 46 years who reported menopause, and 102 of these were taking HRT. The age group 26–45 was not included in further analyses because pathological conditions underlying early menopause might introduce unknown confounders, and because the 19 younger menopausal women not taking HRT would constitute a small and possibly biased reference group.

### Questionnaire

The first part of the questionnaire contained 12 questions identical to those asked in the ECRHS I stage 1. These items covered respiratory symptoms, asthma medication, and hay fever. Asthma was defined as currently using asthma medication and/or having had asthma attacks during the last 12 months, wheeze as having had wheeze during the last 12 months, night symptoms as waking with tightness in chest or waking with shortness of breath, and hay fever as currently having hay fever or nasal allergies. Three or more asthma symptoms were defined based on the following eight symptoms: wheeze, wheeze with shortness of breath, wheeze without cold, waking with tightness in chest, waking with shortness of breath, waking with cough, asthma attacks, and current asthma medication.

The second part of the questionnaire included 52 items covering various aspects including factors related to hormonal status in women. Menopause was defined as answering “yes” to the question “Have you reached the menopause (6 or more months since your last menstruation)?”. HRT was defined as answering “yes” to the question “Are you using hormones/hormone replacement therapy?”. In some centres HRT was only registered in women answering “yes” to having reached the menopause. The women were also asked about pregnancy, use of oral contraceptives, age of menopause, and date of the last menstrual bleeding.

BMI was based on self-reported weight and height and calculated as kg/m². Smoking history was assessed by two questions: “Are you a smoker?” and “Are you an ex-smoker?” Based on these, three groups were defined (never smokers, ex-smokers, and current smokers). Type of dwelling (detached, semi-detached, apartment, other) was used as a proxy for social class, “detached” corresponding to upper social class, etc. A socioeconomic index based on current occupation was available in four centres (Bergen, Gothenburg, Uppsala, and Tartu). In these centres the type of dwelling was strongly correlated with socioeconomic index.

‡‡Asthma and hay fever.
(p<0.001), and analyses with adjustment for this variable gave similar results as when adjusting for type of dwelling.

**Statistical analysis**

Logistic regression models were used to assess the effects of menopause and of HRT on asthma and hay fever. The number at risk fluctuated slightly from outcome to outcome because of a varying number of missing data for each variable. Adjustments were made for age (5 year categories), BMI (kg/m²), smoking habits (never, ex, and current smoker), study centre, and social class (type of dwelling). Adjustments were made for age (5 year categories), BMI (kg/m²), smoking habits (never, ex, and current smoker), study centre, and social class (type of dwelling).

Analyses of HRT were stratified according to BMI categorised in tertiles. Based on the results from the stratified analyses, the two upper tertiles were grouped together post hoc and the differences in the effects of HRT on asthma between lean and heavier women were analysed by including interaction terms of BMI and HRT in the logistic regression models. Similarly, logistic regression models were used to assess the effects of BMI (as a continuous variable) on asthma and hay fever; analyses were stratified by HRT use and an interaction term between BMI and HRT was included to assess the statistical significance of differences in BMI effects between subjects using or not using HRT. Potential heterogeneity between centres was studied by meta-analyses according to DerSimonian and Laird. The analyses were carried out using the statistical software program Stata 7.0 (Stata Corporation, College Station, Texas, USA).

**RESULTS**

Of 2206 women aged 46–54 years, 540 (24%) were using HRT at the time of the study. There was some variation between centres, with HRT being more widely used in Reykjavik and Bergen and less used in Tartu and Aarhus compared with the Swedish centres (table 1). In total, 844 women reported that they were menopausal (table 1). Women taking HRT were leaner, were more often smokers, and more often lived in a semi-detached house than women not taking HRT.

Asthma, wheeze, or hay fever did not differ between premenopausal and postmenopausal women, while there was a borderline significant association between night symptoms and menopause (table 2).

Asthma, asthma symptoms and hay fever, but not night symptoms, were significantly more common among women using HRT (table 3). There was no significant heterogeneity between centres in the association of HRT with asthma or wheeze (p heterogeneity = 0.84 and 0.35 for asthma and wheeze, respectively; fig 1).

When stratifying by BMI in tertiles, HRT was significantly associated with a higher risk for asthma, wheeze and hay fever only among lean women (table 4). The associations between HRT and asthma and wheeze in women in the lower BMI tertile were significantly stronger than the corresponding associations in women in the medium and upper tertiles (p heterogeneity = 0.020 and 0.026, respectively).

Increasing BMI was associated with more asthma and asthma symptoms, but not with hay fever (table 5).

Stratifying by use of HRT, an association between asthma and BMI was observed in women not taking HRT (OR 1.10; 95% CI 1.05 to 1.14 per kg/m²; fig 2A) while no such association could be detected in women taking HRT (OR 1.00;
The difference in the associations between asthma and BMI according to use of HRT was significant ($p_{\text{interaction}} = 0.046$).

The associations between HRT and asthma, wheeze and hay fever were only significant in never smokers (table 6), although the differences between smoking groups were not significant ($p_{\text{interaction}} = 0.19, 0.6, \text{and } 0.4$ for asthma, wheeze, and hay fever, respectively).

**DISCUSSION**

The prevalence of diagnosed asthma, asthma symptoms, and allergy was higher among HRT users in a multicentre, population based, cross sectional survey of Northern European perimenopausal women. This was consistent between centres with different prescription practices. The risk for asthma related to HRT use was significantly greater in lean women than in heavier women, and this interaction in the effects of HRT and BMI on asthma was significant. The well documented association of asthma with BMI was observed only in women not taking exogenous sex hormones, while no significant association between asthma and BMI was found among HRT users. Exogenous oestrogens therefore appear to interfere with the mechanism causing more asthma among overweight women, resulting in a similar high prevalence of asthma in lean HRT users as that observed in obese women not taking HRT.

The observed higher prevalence of asthma among HRT users is in agreement with findings from the two large cohort studies, the Copenhagen City Heart Study and the Nurses' Health Study.3–5 The interaction between BMI and HRT in the effects on asthma is supported by the Nurses’ Health Study in which the relative risk for HRT on asthma was 3.09 in lean women and 1.58 in heavier women.4 An association between HRT and hay fever has not been reported previously. Our study supports the findings of Lange et al6 who noted a stronger association of HRT with asthma among never smokers, possibly due to anti-oestrogen effects of smoking.6 Our findings are not necessarily contradictory to those of Carlson et al6 as we did not have data on lung function and our study population comprised much younger women.

The main limitation of the present study is its cross sectional design. Due to the lack of information about when the women started using HRT, we do not know with certainty

95% CI 0.92 to 1.08 per kg/m²; fig 2B). The difference in the associations between asthma and BMI according to use of HRT was significant ($p_{\text{interaction}} = 0.046$).
whether or not HRT preceded asthma. Self-reported use of HRT is considered to be reliable. We did not have information about the type of HRT, but Barr et al did not observe differences with regard to type of HRT. Differential misclassification of asthma related to HRT use is a possibility; women taking HRT might have their asthma diagnosed more often because of a higher health awareness or more frequent contact with a doctor. The association between asthma and obesity might also be influenced by doctor bias. However, it seems unlikely that these sources of error explain our findings because the associations were consistent between centres with different prescription practices, the findings were similar for doctor diagnosed asthma and asthma symptoms such as wheeze, adjustment for social class did not alter the effects, and the associations between asthma and HRT differed significantly between lean women and those of normal weight. This interaction between HRT and BMI is biologically plausible but difficult to attribute to systematic error.

Women in the age group 46–54 years as included in this study are usually in the perimenopausal transition. The mean age of onset for the perimenopausal transition is 46 years and the mean duration is 5 years. This is the age when the climacteric symptoms are most frequent and the use of HRT most relevant. There is a possibility for residual confounding by menopausal status, but self-reported menopausal status is considered reliable even though some caution must be exerted. Differential misclassification of respiratory night symptoms as related to menopause could be suspected; night symptoms as opposed to other asthma symptoms appeared to be more common in menopausal women and less common in those taking HRT. There are some discrepancies in the current available literature about the role the onset of menopause plays in the development of pre-existing or new asthma and allergy. Some studies show a reduced asthma risk in naturally menopausal women1 while others suggest that asthma may start or worsen with the menopause. In our study menopause in itself was not significantly associated with asthma or hay fever.

Our study shows that the association between HRT and asthma appears to be modified by BMI. This is biologically plausible as there is a close interplay between sex hormones, fatty tissue, and metabolic status. A similar interaction has been described for breast cancer where the increase in relative risk among HRT users was greatest in lean women. The association between asthma and BMI is well documented although not fully understood. BMI is closely related to insulin resistance (IR), and we suggest that the association between asthma and BMI may be due to the pro-inflammatory effects of IR. There is no direct evidence linking asthma with IR, but several studies have shown an association between lung function and IR and a previous analysis of the present population showed an association between asthma and menstrual irregularity which is often a manifestation of IR.

The effects of oestrogens on the airways appear to be complex. Both direct pro-inflammatory effects and indirect beneficial metabolic effects are described. Oestrogens are closely related to BMI, which is the strongest marker of oestrogen levels in postmenopausal women. IR is intimately involved in the regulation of local oestrogen

production. We therefore hypothesise that exogenous oestrogens and BMI act on the airways in part through common pathways, where inflammation associated with IR might have an important role. In lean women with low IR the direct pro-inflammatory effects of HRT could be predominant, while in heavier and more insulin resistant women such effects might be counterbalanced by an oestrogen related reduction in IR.

In conclusion, our study shows an association between HRT and asthma and hay fever, and confirms the association of obesity with asthma. This study also reveals an interaction between HRT and BMI in the effects on asthma, HRT increasing the risk of asthma in lean women to the same level as that observed in obese women. These findings are fairly convincing as the interaction with BMI is biologically plausible and difficult to explain as error, even if the study design is not ideal. This study therefore indicates that asthma and allergy may be side effects of HRT, at least in subgroups of women. Furthermore, obesity and exogenous oestrogens may be involved in the pathogenesis of asthma through partly common pathways. Future studies of the effects of HRT on the airways should be conducted in representative general population samples, taking into account the possibility that the effects of oestrogens might be dependent on BMI or metabolic status. Likewise, further studies of asthma and BMI should take into consideration the hormonal status.

Clinical Evidence—Call for contributors

Clinical Evidence is a regularly updated evidence-based journal available worldwide both as a paper version and on the internet. Clinical Evidence needs to recruit a number of new contributors. Contributors are healthcare professionals or epidemiologists with experience in evidence-based medicine and the ability to write in a concise and structured way.

Areas for which we are currently seeking contributors:

- Pregnancy and childbirth
- Endocrine disorders
- Palliative care
- Tropical diseases

We are also looking for contributors for existing topics. For full details on what these topics are please visit www.clinicalevidence.com/ceweb/contribute/index.jsp

However, we are always looking for others, so do not let this list discourage you.

Being a contributor involves:

- Selecting from a validated, screened search (performed by in-house Information Specialists) epidemiologically sound studies for inclusion.
- Documenting your decisions about which studies to include on an inclusion and exclusion form, which we keep on file.
- Writing the text to a highly structured template (about 1500-3000 words), using evidence from the final studies chosen, within 8-10 weeks of receiving the literature search.
- Working with Clinical Evidence editors to ensure that the final text meets epidemiological and style standards.
- Updating the text every 12 months using any new, sound evidence that becomes available.

The Clinical Evidence in-house team will conduct the searches for contributors; your task is simply to filter out high quality studies and incorporate them in the existing text.

If you would like to become a contributor for Clinical Evidence or require more information about what this involves please send your contact details and a copy of your CV, clearly stating the clinical area you are interested in, to CECommissioning@bmjgroup.com.

Call for peer reviewers

Clinical Evidence also needs to recruit a number of new peer reviewers specifically with an interest in the clinical areas stated above, and also others related to general practice. Peer reviewers are healthcare professionals or epidemiologists with experience in evidence-based medicine. As a peer reviewer you would be asked for your views on the clinical relevance, validity, and accessibility of specific topics within the journal, and their usefulness to the intended audience (international generalists and healthcare professionals, possibly with limited statistical knowledge). Topics are usually 1500-3000 words in length and we would ask you to review between 2-5 topics per year. The peer review process takes place throughout the year, and our turnaround time for each review is ideally 10-14 days.

If you are interested in becoming a peer reviewer for Clinical Evidence, please complete the peer review questionnaire at www.clinicalevidence.com/ceweb/contribute/peerreviewer.jsp

**Authors’ reply**

Unfortunately, the paper by Maziak et al. published in *Allergy* was listed as reference number 18 instead of number 21 in the reference list of our paper. We apologise for any misunderstanding which may have arisen from this error. A correction is published below.

In the paper by Maziak et al. the prevalences in 1994/5 and 1999/2000 are compared. As we know from our own studies, trend analyses based on (only) two time points may be difficult and should be interpreted with caution. Indeed, in their investigation Maziak et al. did not find a significant increase in the lifetime prevalence of asthma and hay fever, except in one subgroup. The effect found in 13-14 year old girls could also be due to a former underdiagnosis of asthma in girls, as discussed in their paper.

Since our results are based on six cross sectional surveys, we consider the title and the conclusion—that we did not see an increase in asthma and allergies from 1992 to 2001—to be appropriate.

I Zöllner

---

**CORRECTIONS**

In the paper entitled “No increase in the prevalence of asthma, allergies, and atopic sensitisation among children in Germany: 1992-2001” by I K Zöllner et al which appeared in the July 2005 issue of *Thorax* (2005;60:545-8), the authors apologise for a mistake which occurred in the reference list. Reference number 18 should be number 21 and references 19–21 should be listed as 18–20.

doi: 10.1136/thx.2005.040444corr1

The paper entitled “Anticholinergics in the treatment of children and adults with acute asthma: a systematic review with meta-analysis” by G J Rodrigo and J A Castro-Rodriguez (10.1136/thx.2005.040444) has been published previously on 17 June 2005 as a *Thorax* Online First article but under the incorrect DOI (10.1136/thx.2005.047803). The publishers apologise for this error. The definitive version of the article can be found at the following citation: *Thorax* 2005;60:740-6.

doi: 10.1136/thx.2005.040881corr1

In the paper entitled “Hormone replacement therapy, body mass index and asthma in perimenopausal women: a cross sectional survey” by F Gómez Real et al published in the January 2006 issue of *Thorax* (2006;61:34–40), the fourth author should be K A Franklin, not K Franklin.
