Delayed-onset bronchiolitis obliterans with organising pneumonia associated with massive acetic acid steam inhalation

A 34-year-old worker had massive exposure to acetic acid steam from an explosion in a chemical factory. At the emergency department respiratory distress, hoarseness and swelling of the oropharyngeal mucosa were noted. The chest radiograph showed bilateral infiltration (fig 1). After being diagnosed with inhalation injury and chemical pneumonitis, he was prophylactically intubated and given parenteral steroid with prophylactic antibiotics. Diagnostic fiberoptic bronchoscopy revealed diffuse tracheobronchial mucosal redness and friability (fig S1A, B available online only). Scattered throughout the airway were multiple corrosive ulcerations. A follow-up thin-section CT scan at day 15 showed ground-glass attenuation in the bilateral upper lungs (fig S1C, D available online only). Delayed-onset bronchiolitis obliterans organising pneumonia (BOOP) due to acetic acid steam inhalation was diagnosed. He died of an episode of methicillin-resistant *Staphylococcus aureus* infection of the bloodstream with multiple organ failure 1 month later.

The natural course of pulmonary injury associated with acetic acid steam exposure has not been documented. Our patient experienced a biphasic clinical response characterised by acute pulmonary oedema followed by delayed-onset BOOP, similar to that observed in other cases of irritant gas exposure. The most common symptoms of BOOP are a progressive dry cough, effort dyspnoea, low-grade pyrexia and malaise. Patients with BOOP rarely present with a large amount of haemoptysis and this posed a great diagnostic challenge initially.

**Learning points**

- Massive exposure to acetic acid steam may cause a biphasic pulmonary disease, acute pulmonary oedema followed by BOOP, similar to that observed in other cases of irritant gas exposure.
- In patients with irritant gas exposure and compatible radiographic findings, massive haemoptysis is a possible presentation that warrants consideration of BOOP.

**Figure 1** Initial chest radiograph showing bilateral perihilar infiltrates.

**Figure 2** (A) High-resolution CT scan showing diffuse ground-glass attenuation in the bilateral upper lungs. Scattered areas of air trapping are visible (arrows). (B) Lower section showing only scattered peribronchovascular ground-glass attenuation (arrow). Patchy consolidation is evident (arrowhead).
