Changes in prevalence and load of airway bacteria using quantitative PCR in stable and exacerbated COPD

Davinder S Garcha,1 Sarah J Thurston,1 Anant R C Patel,1 Alexander J Mackay,1 James J P Goldring,1 Gavin C Donaldson,1 Timothy D McHugh,2 Jadwiga A Wedzicha1

ABSTRACT
Background Prevalence and load of airway bacteria in stable and exacerbated chronic obstructive pulmonary disease (COPD) has been previously studied using microbiological culture. Molecular techniques, such as quantitative PCR (qPCR), may be more informative.

Methods In this study, 373 sputum samples from 134 COPD outpatients were assessed for prevalence and load of typical airway bacteria (Haemophilus influenzae, Streptococcus pneumoniae, Moraxella catarrhalis) by multiplex qPCR, with 176 samples analysed for atypical bacteria. Paired stable and exacerbated typical bacteria data were compared in 52 patients. We compared routine culture with qPCR in 177/373 samples.

Results Typical bacteria were more prevalent in exacerbation than stable-state paired samples: 30/52 (57.7%) vs. 14/52 (26.9%); p=0.001. In patients who were bacteria-positive at both time points, mean (±1 SEM) load was significantly higher at exacerbation than stable state (108.5±0.3 vs. 107.2±0.5 cfu/ml), constituting a 20-fold increase (p=0.011). qPCR was more discriminatory at detecting typical bacteria than microbiological culture (prevalence 59.3% vs. 24.3%; p<0.001). At stable state, higher airway bacterial load correlated with more severe airflow limitation (FEV1% predicted) (r=−0.299; p=0.033) and higher inhaled corticosteroid dosage (r=0.382; p=0.008). Mean C-reactive protein was higher in bacterial-associated exacerbations (35.0 Vs 25.1 mg/L; p=0.032).

Conclusions Airway bacterial prevalence and load increase at COPD exacerbations and are an aetiological factor. qPCR is more discriminatory than culture, identifying higher airway bacterial prevalence. Exacerbations associated with bacterial detection showed a higher mean C-reactive protein level in the stable state, airway bacterial load is related to more severe airflow limitation and higher inhaled corticosteroid dosage used.

INTRODUCTION
Chronic obstructive pulmonary disease (COPD) is an inflammatory condition caused by an abnormal response to noxious gases and particles.1 COPD is associated with considerable morbidity and mortality and has been projected to become the fourth highest cause of death by 2030.2 Acute exacerbations of COPD are episodes which are characterised by a worsening of respiratory symptoms associated with variable degrees of physiological deterioration.3 These events are a major cause of morbidity and mortality globally, and COPD exacerbations are a leading cause of hospital admissions.3

Lower airway bacterial colonisation (LABC) is a common and important feature of COPD, and the commonly isolated organisms are S pneumoniae, H influenzae and M catarrhalis,4 5 although most studies investigating LABC have used culture techniques. LABC has been shown to be related to an increase in airway inflammation, exacerbation frequency and lung function decline.5–8

Previous studies suggest that the majority of exacerbations have an infectious aetiology—with approximately half these events associated with culture of potentially pathogenic airway bacteria, similar to those found in the stable state.9 Positive cultures of Pseudomonas aeruginosa have also been shown to be associated with COPD, but more commonly in advanced disease.10

Key messages

What is the key question?
► Is there a change in prevalence and load of airway bacteria in COPD patients between the stable state and exacerbation, and what is the association between bacteria and lung function, inhaled corticosteroid dosage and systemic inflammation?

What is the bottom line?
► Airway bacterial prevalence and load, as detected by qPCR, increases significantly at COPD exacerbation, with quantitative molecular techniques offering a more accurate reflection of prevalence and load compared with conventional methods. Higher bacterial load is correlated with poorer lung function and higher inhaled corticosteroid dosage in stable COPD patients; bacterial presence at exacerbation is associated with higher systemic inflammation.

Why read on?
► Increased airway bacterial load is a key aetiological factor in acute exacerbations of COPD, and also relates to disease severity in the stable state. Inhaled corticosteroid usage may affect bacterial colonisation, and thus increase susceptibility to pneumonia.
Chronic obstructive pulmonary disease

To date, the vast majority of analysis of bacterial prevalence and load has been based on culture, but there is little on PCR comparison with culture. The use of culture-independent techniques, such as quantitative PCR (qPCR), has not been extensively studied in the context of atypical airway bacteria, which are characteristically difficult to culture (C pneumoniae, L pneumophila and M pneumoniae), with one previous study showing no association with COPD exacerbations. Conversely, serological analysis has suggested an association, and further examination is warranted.

The objective of this study was to investigate the prevalence and load of typical and atypical airway bacteria in COPD using modern molecular techniques. We also analysed prevalence and load at the stable and exacerbation states, and compared qPCR with routine microbiological culture.

METHODS
Recruitment criteria
This study involved 134 subjects enrolled in the London COPD cohort between January 2007 and March 2011. The patients form part of a rolling cohort used to prospectively investigate the mechanisms and aetiology of COPD exacerbations, as previously described by our group. Patients were included if the forced expiratory volume in one second (FEV1) was ≤80% predicted and FEV1/forced vital capacity (FVC) ratio was <0.7, in keeping with GOLD stages II–IV. A history of chronic symptoms (dyspnoea, sputum production, wheeze and cough) was taken, as well as smoking history (number of pack-years smoked, current smoking status). Patients with a history of any other significant respiratory diseases were excluded, as were those unable to complete daily diary cards.

Definitions of clinical states
An exacerbation was defined as new or increased respiratory symptoms for two or more consecutive days, with at least one major symptom (dyspnoea, sputum purulence and sputum volume), and another major or a minor symptom (wheeze, cold, sore throat and cough), the first day of which was defined as the day of onset of the exacerbation. Stable state was defined as no symptom-defined exacerbations for the preceding 4 weeks and the subsequent 2 weeks post-visit.

Clinical assessment
Spirometry was performed in accordance with ATS/ERS guidelines, using a volumetric storage spirometer (Vitalograph 2160, Maids. Moreton, Buckingham, UK). FEV1 was expressed as a percentage of that predicted from age, height and sex. Serum C-reactive protein (CRP) quantification was performed to assess systemic inflammation, using Modular Analytics E 170 Module (Roche, Burgess Hill, UK). Patients recorded inhaled corticosteroid dosage and usage daily on diary cards. Due to variations in dosage by different medications, we applied beclomethasone-equivalence dosage correction, as previously performed by our group.

Sputum collection and processing
Sputum was spontaneously expectorated into a sterile pot in the stable state and/or at exacerbation. All exacerbation visits occurred within 7 days of exacerbation symptom onset. Patient samples were used in a number of different analyses (figure 1).

Following expectoration, sputum plugs were separated from saliva using sterile forceps, with one-third being taken for culture analysis where there was sufficient quantity. The remaining sputum was weighed and suspended in nine times volume of standard isotonic phosphate-buffered saline (PBS). Glass beads were added to this suspension and it underwent homogenisation by vortexing for 15 s, rocking for 15 min (IKA VibraX VXR, Staufen, Germany) and additional vortexing for 15 s. Aliquots of 500 μl were taken for storage at −80°C for subsequent batch processing.

Routine microbiological culture
Qualitative bacterial culture was carried out by the Department of Medical Microbiology, Royal Free Hampstead NHS Trust, London. Briefly, sputum was cultured onto suitable agar for 24 h at 37°C and 5% CO2. Agar types used were Columbia blood agar (general growth media), Chocolate agar (growth of fastidious bacteria), MacConkey agar (growth of Gram-negative bacteria), and CBOA agar (growth of Streptococcus spp.). S pneumoniae was identified through optochin sensitivity testing.

DNA extraction
Homogenised sputum samples underwent heat-kill treatment at 90°C for 50 min before being microfuged at 15,000 g for 10 min. The pellet was washed in 1 ml PBS and spun at 15,000 g for 10 min before removal of supernatant and re-suspension of the pellet in 200 μl of PCR-grade UV-sterilised water (Sigma-W4502). To each sample, 200 μl of 10% Chelex 100 (Sigma C-7901) was added. Samples were incubated for 20 min in a heat block at 56°C. Samples were heated at 95°C for five minutes prior to cooling on ice. Samples were then spun in a microfuge at 16,000 g for 10 min. Supernatant, containing extracted DNA, was transferred to a fresh UV-sterilised 1.5 ml tube and stored at 4°C.

Multiplex qPCR detection of bacteria
Real-time multiplex qPCR was performed on S pneumoniae, H influenzae and M catarrhalis, targeting Spn9802 (gene fragment), H influenzae P4 lipoprotein gene, and copB outer-membrane-protein gene, respectively. Both Spn980216 and copB17 profiles used previously validated qPCR primers and probes, ensuring no cross-reactivity with related oral species. The H influenzae P4 lipoprotein gene target was established in-house. This was confirmed to have no cross-reactivity with other Haemophilus species as well as a number of Streptococcus spp., M catarrhalis, Bordetella pertussis, Candida spp., P aeruginosa, Escherichia coli, Neisseria meningitidis, Acinetobacter spp., Legionella pneumophila, Klebsiella pneumoniae, methicillin-resistant Staphylococcus aureus and Corynebacterium diphtheriae. An internal amplification control (IAC), targeting the

Figure 1 COPD patient groups analysed. Patients may have been in more than one subanalysis. For paired analysis, stable samples were obtained <365 days prior to exacerbation (the nearest stable sample to the exacerbation was used).
PhyB gene of *Solanum tuberosum*, was used in order to detect any PCR inhibition, incorporated in the PCR mastermix. The following positive control strains were used: *S pneumoniae* ATCC strain 49619; *H influenzae* ATCC strain 10211; *M catarrhalis* ATCC strain 25238. The minimum limit of detection used in this study was 10⁴ colony-forming units (cfu)/ml.

A separate multiplex qPCR was performed to detect *C pneumoniae*, *L pneumophila* and *M pneumoniae*, targeting RNA-polymerase β-chain gene, MIP gene and F1 adhesion protein gene, respectively. *C pneumoniae* primer/probe set was a previously validated set. *M pneumoniae* and *L pneumophila* were developed in-house and shown to have no cross-reactivity with related species and other oral flora. The PCR was performed with two types of mastermix, one of which was spiked with an IAC (*L pneumophila* DNA). Primer and probe details are listed in web-only files in the appendix. Normalisation of qPCR results was performed by correcting Ct values of the IAC in positive samples according to its corresponding value in no-template-control samples.

### Statistical analysis
Data were analysed using PASW Statistics V.18 (SPSS Inc.). The Kolmogorov–Smirnov test for normality was applied. Clinical data with normal distribution are described in mean (±SD). Differences between groups were analysed by independent-samples t test, paired-samples t test, Mann–Whitney U test or one-way ANOVA, dependent upon the sample population being investigated. Relationships between continuous variables were analysed using Pearson’s or Spearman’s correlation in a univariate analysis, or by linear regression in a multivariate analysis. Frequency distribution was explored by χ² analysis. A probability of p<0.05 was considered to be statistically significant.

### Ethical considerations
The study was approved by the Royal Free Research Ethics Committee, and all patients gave informed written consent.

### RESULTS

#### Patient characteristics
Sputum samples from 134 COPD patients were examined. There were no clinically or statistically important differences in stable-state clinical characteristics between the subgroups (table 1).

#### Typical bacteria prevalence and load determined by qPCR
Typical bacterial prevalence by qPCR was higher in exacerbation sputum samples compared with stable samples (74/151 bacterial isolates (56.5%) vs 107/242 (44.2%) respectively, p=0.024).

In samples positive for bacteria, mean (±1 SEM)-typical bacteria count was significantly higher during exacerbation, at 10²³.₀₂ cfu/ml (in absolute numbers 2×10⁶ cfu/ml), compared with the stable state, with 10²².₀₂ cfu/ml (in absolute numbers 2×10⁵ cfu/ml), a 10-fold increase, and significantly different (p<0.001) in an unpaired analysis (figure 2). *H influenzae* was the most prevalent species, both in the stable state (21.9%) and at exacerbation (26.0%). *M catarrhalis* was significantly more prevalent at exacerbation (16.5%) compared with the stable state (7.4%) (p=0.005). Mean (±1 SEM) bacterial load of both *S pneumoniae* and *H influenzae* was significantly higher at exacerbation than at stable state: 10²⁻².₀₁ (p=0.005) vs 10²⁻²⁻².₀₂ cfu/ml, p=0.045 and 10²⁻²⁻².₀₁ vs 10²⁻²⁻².₀₂ cfu/ml, p<0.001, respectively.

**Typical bacteria prevalence and load in paired stable and exacerbation samples**
Fifty-two pairs of stable and exacerbation samples from 52 patients showed significantly higher cumulative prevalence of typical bacteria at exacerbation compared with the stable state (67.3% vs 30.8%; p<0.001). Fourteen stable-state samples (26.9%) were positive for at least one bacterium compared with 30 exacerbation-state samples (57.7%) (p=0.001). In paired samples which were bacteria-positive at both stable and exacerbation state (n=12), the mean load was approximately 20-fold higher at exacerbation than in the stable sample (10²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻²⁻².chomp This page includes information about library updates and version controls. No significant differences were seen between the groups. Paired analysis refers to patients with paired stable and exacerbation-state samples (the nearest stable-state sample prior to exacerbation was used in this analysis). Data is presented as percentage value or mean±SD as appropriate.

**Figure 2** Quantitative PCR comparison of load of typical airway bacteria in stable COPD (n=242) and exacerbation (n=131) in unpaired samples. Species: SP = *Streptococcus pneumoniae*; MC = *Moraxella catarrhalis*, HI = *Haemophilus influenzae*.  

seen at exacerbation (13/52, 25%) (figure 3A). *M catarrhalis* showed a significant increase in prevalence at exacerbation (10/52, 19.2%), increasing from 2/52 (3.8%) at the stable state (p=0.014). *S pneumoniae* prevalence was significantly higher at exacerbation (15/52, 25.0%) than during stable state (3/52, 5.8%) (p=0.002).

**Comparison of qPCR with culture for the detection of typical bacteria**

Culture and qPCR for typical bacteria were compared in 177 samples (105 stable and 72 exacerbation samples) from 74 patients. qPCR was far more discriminatory at detecting typical bacteria than culture (105/177 positive samples (59.3%), vs 43/177 (24.3%), p<0.001). This finding was replicated in terms of individual bacterial species: *H influenzae* 50.5% PCR-positive versus 15.8% culture-positive, (p=0.001); *S pneumoniae* 14.1% versus 5.1%, (p=0.004); *M catarrhalis* 14.7% versus 3.4%, (p<0.001) (figure 4).

Positive culture identification and negative qPCR identification was seen for *H influenzae* in 4/177 samples (2.3%); for *S pneumoniae* in 4/177 samples (2.3%); for *M catarrhalis* in 1/177 samples (0.6%).

**Effect of typical bacteria on lung function in stable state and at exacerbation**

Higher bacterial load was significantly correlated to disease severity in the stable state (FEV1 % predicted); r=−0.299; p=0.053 (figure 5). In a multivariate analysis, the relationship between FEV1 and airway bacterial load remains significant after allowance of either age (p=0.036) or smoking status (p=0.046), although it just misses statistical significance when both age and smoking status are included in the model (p=0.057).

Percentage (±SD) change in FEV1 (from stable state) with *H influenzae*-associated exacerbations (n=10) was −17.4% (±15.8%), and in exacerbations which had no *H influenzae* presence (n=47), the change was −5.9% (±20.0%). This difference was not statistically significant (p=0.09).

**Airway bacterial load association with inhaled corticosteroid usage**

Forty-seven (92.2%) patients who had bacteria detected in the stable state had inhaled corticosteroid usage recorded. Median (IQR) beclomethasone-equivalent dosage was 2000 (640–2000) μg daily. In a univariate analysis, higher airway bacterial load was also significantly correlated to higher inhaled corticosteroid dosage (corrected for beclomethasone equivalence);
r=0.382; p=0.008. This relationship remains significant in a multivariate analysis including age, smoking status and FEV₁ % predicted (p=0.022).

Systemic inflammation is related to airway bacterial presence during exacerbations

Levels of CRP, a marker of systemic inflammation, were significantly related to presence of typical airway bacteria at exacerbation. CRP was measured in 119 exacerbation samples. Exacerbations with bacterial detection (n=58) showed significantly higher mean CRP compared with exacerbations with no bacterial detection (n=61); 35.0 versus 25.1 mg/l, p=0.032.

Analysis of COPD patient samples for atypical bacteria

A total of 176 samples, from 80 patients, were investigated for presence of the atypical bacteria (C pneumoniae, L pneumophila, M pneumoniae). Of these, 97 were stable samples, and 79 were exacerbation samples. Five samples were positive for L pneumophila (four stable, one exacerbation), and one stable sample was positive for M pneumoniae. No relationship was observed between atypical bacterial load and clinical outcome: Mean bacterial load for L pneumophila was 10^{4.46±0.40}, and for the M pneumoniae sample it was 10^{6.4} cfu/ml.

DISCUSSION

This is the largest study, to date, to use molecular techniques for detection of airway bacteria, and also the first to complimentarily evaluate typical and atypical bacteria in a well-characterised cohort of COPD patients. We have explored the relationship between airway bacterial prevalence and load in stable COPD patients and at exacerbations. At exacerbation, there was a marked increase in bacterial load in colonised patients, with an absolute increase in the region of 20-fold being identified in positive samples. We have conclusively demonstrated that qPCR is more discriminatory than culture at detecting each of these three main airway bacterial species. Of further note, we have also conclusively quantified typical airway bacteria in a cohort of COPD patients, with a concomitant illustration of significant increases in prevalence and load of three of the most commonly isolated bacteria seen in such subjects, at exacerbation. This provides further support to previous studies which hypothesise that alterations in ‘normal’ bacterial colonisation may trigger acute exacerbations of COPD.28 This study has not examined the strain-switching hypothesis previously put forward.29 However, strain acquisition is associated with an increase in bacterial load. Further work is needed to explore whether differences in stable and exacerbation loads are related to the same strain or different strains of specific bacterial species.

For the first time, we have also shown a significant relationship between airway bacterial load and inhaled corticosteroid dosage at the time of sampling in stable patients; this effect was independent of age, smoking status and disease severity. Findings from the TORCH and INSPIRE randomised controlled trials have indicated that inhaled corticosteroid use is related to increased frequency of developing pneumonia in COPD patients.30–32 Our data suggests that the increase in airway bacterial colonisation may play a part in increasing susceptibility to pneumonia in COPD.

This study was limited to the three most commonly detected organisms, and it is probable that other organisms also contribute to the microbiome. However, recent detailed studies in small numbers of subjects have identified only the presence of commensals in addition to the common bacteria we studied, and it is unlikely that other bacteria are playing a significant role.33 34 P aeruginosa was not studied in this analysis as its culture detection rate was very low in the London COPD cohort (<1%). It is difficult to differentiate between those strains that were infective and those which were colonising, due to the fact...
that colonising strains are very likely to also appear at exacerbation. The different methodological approaches required are
beyond the scope of this study.

The potential role of atypical bacteria in COPD was important to investigate with qPCR, as they are characteristically difficult to culture, and if found at high prevalence or load, could have major implications for therapy. A previous study found little evidence of atypical bacterial colonisation in a qPCR analysis of 248 sputum samples from COPD patients, with just one sample positive for Legionella spp. The current study investigated the rate of these bacteria in COPD patients and found low prevalence, with one exacerbation sample (1.5%) identified with presence of L. pneumophila. Atypical bacteria are, therefore, not major pathogens in COPD, either in the stable state or at exacerbation, and do not need specific therapy.

This study shows that at COPD exacerbations, airway bacterial prevalence and load increase significantly, and are an important aetiological factor driving the event. The presence of increased total bacterial load in the stable state and relationship to disease progression suggests that targeted antibiotic therapy for colonised patients may be beneficial. qPCR is more discriminatory than culture, identifying higher airway bacterial prevalence, and thus, should have an important role in routine clinical microbiological practice.

Acknowledgements The authors wish to thank the Medical Research Council (UK) for funding the London COPD cohort and also a capacity-building PhD studentship for D Garcha. We also wish to thank Ray Sapsford for his assistance in rapidly processing sputum samples following collection, and Dr Clare Ling and Julianne Lockwood for their invaluable assistance in multiplex PCR set-up. We are thankful to all patients of the London COPD cohort for dedicating their time and energy to assist others with COPD.
