Smoking Termination Opportunity for inPatients (STOP): superiority of a course of varenicline tartrate plus counselling over counselling alone for smoking cessation: a 12-month randomised controlled trial for inpatients

ABSTRACT
Rationale Smoking cessation interventions in outpatient settings have been demonstrated to be cost effective. Given this evidence, we aimed to evaluate the effectiveness of varenicline tartrate plus Quitline-counselling compared with Quitline-counselling alone when initiated in the inpatient setting.

Methods Adult patients (18–75 years) admitted with a smoking-related illness to three hospitals, were randomised to receive either 12-weeks of varenicline tartrate plus Quitline-counselling, (n=196) or Quitline-counselling alone, (n=196), with 12-months follow-up.

Results For the primary analysis population (intention-to-treat), the proportion of subjects who remained continuously abstinent were significantly greater in the varenicline plus counselling arm (31.1%, n=61) compared with counselling alone (21.4%, n=42; RR 1.45, 95% CI 1.03 to 2.03, p=0.03).

Conclusions The combined use of varenicline plus counselling when initiated in the inpatient setting has produced a sustained smoking cessation benefit at 12-months follow-up, indicating a successful opportunistic treatment for smokers admitted with smoking related illnesses.

Trial registration http://www.clinicaltrials.gov/ ClinicalTrials.gov identification number: NCT01141855.

Smoking accounts for 15% of all deaths, 80% of all lung cancer deaths and is responsible for the greatest disease burden in Australia.1 In the outpatient setting, varenicline tartrate has been shown to raise the odds of quitting smoking by 2.5–3-times compared with placebo, 12-months after quitting.2–3 Of the available primary prevention initiatives, general practitioners (GPs) significantly under-use Quitline services or medications, and only 6% of patients who are encouraged to use Quitline by their GP do so.4 Abstinence from smoking, following a hospital admission, has been associated with reduced readmissions, with patients who stop smoking by the time of discharge, after 5 year follow up, having up to 31% less hospital admission bed days, 15% less outpatient visits and 50% less bed days used compared with those that continue smoking.5–7 Yet to our knowledge initiation of varenicline has not been evaluated in an inpatient-initiated setting, where the opportunity for a targeted secondary prevention programme combined with counselling could be used. Inpatient stays may provide an opportunity to use a patient’s reflection upon their illness (ii) bedside phone to ensure initial contact with Quitline counselling service, and (iii) observation period for any medication related adverse effects. We therefore conducted a randomised, multicentre controlled clinical trial, with a 12-week treatment phase and 12-months follow-up.

Participants were recruited following admission to hospital due to a serious smoking related illness, within the disciplines of respiratory, cardiology, neurology and vascular medicine. They were aged 18–75 years, smoked at least 10 cigarettes per day over the past 12 months with a plan for at least 6-months of smoking cessation. At the end of the 12-week treatment period, 12-months after admission, patients were randomised to receive either varenicline (titrated from 0.5mg daily to 1mg twice daily) plus Quitline counselling (n=196) or Quitline counselling alone (n=196).

For the primary outcome of continuous abstinence at 12-months, the proportion of successful subjects in the varenicline plus counselling arm was significantly greater with both arms showing reuptake of smoking; however, this gap remains significant despite the plateau (figure 1).

At the end of the 12-week treatment period, the abstinence for varenicline plus counselling over counselling alone and adverse event profile were similar to results reported in outpatient studies.2 Targeting inpatients during the period of hospital confinement where admissions result from smoking related diseases, utilises an opportunity for initiation of best practice treatment. The STOP trial has provided a real world assessment of varenicline in the inpatient setting, demonstrating effectiveness for patients following an acute smoking-related admission.
