Implementation of the Needs Assessment Tool for patients with interstitial lung disease (NAT:ILD): facilitators and barriers

A Needs Assessment Tool (NAT) was developed previously to help clinicians identify the supportive/palliative needs of people with interstitial lung disease (ILD) (NAT:ILD). This letter presents barriers and facilitators to clinical implementation. Data from (1) a focus group of respiratory clinicians and (2) an expert consensus group (respiratory and palliative clinicians, academics, patients, carers) were analysed using Framework Analysis. Barriers related to resources and service reconfiguration, and facilitators to clinical need, structure, objectiveness, flexibility and benefits of an ‘aide-mémoire’. Identified training needs included communication skills and local service knowledge. The NAT:ILD was seen as useful, necessary and practical in everyday practice.

INTRODUCTION

The Needs Assessment Tool: Progressive Disease-Cancer (NAT:PD-C) was developed to help non-palliative care clinicians identify supportive and palliative needs of people with cancer and their informal carers. It reduced unmet needs without increasing consultation time.

In response to unmet supportive and palliative care needs of people with interstitial lung disease (ILD) and national guidance, the NAT:PD-C was adapted for people with ILD (NAT:ILD). It prompts clinicians to assess in four sections the holistic needs of patient well-being (one section), their informal carers’ needs (two sections) with additional prompts for information needs and triage for specialised palliative care.

We aimed to identify facilitators and barriers affecting potential clinical implementation of the NAT:ILD.

METHODS

We used a qualitative approach, with a focus group and an expert consensus group.

Participants and sampling strategy

Focus group

A convenience sample of ILD clinicians at one tertiary referral centre was invited. The clinical service had links with the palliative care breathlessness intervention service but a palliative specialist was not part of the ILD multidisciplinary team (MDT).

Expert consensus group

Participants, from hospital and community settings, comprised ILD and general respiratory clinicians (doctors, nurses, physiotherapists); patients and carers; and research team members.

Data collection

The facilitator (MJL) led both groups through the tool to explore face and content validity. Unprompted comments about implementation arose during discussion, then broad questions were asked about factors that would facilitate or hinder implementation in clinical practice (facilitated by AP). Groups were video and audio-recorded and contemporaneous field notes taken (JB).

Analysis

Framework Analysis was used with anonymised transcripts coded (CR, AP), an analytical framework developed and themes generated. Video observations using cognitive mapping and field notes helped interpretation. Data were managed using NVivo Software (QSR International, V10, 2012). The pragmatic sample size achieved coding and thematic saturation.

Ethics

This was part of a larger adaptation and validation project, approved by NRES (14/NE/0127) and each institution. Focus group participants gave written consent; this was not required for the expert consensus group.

RESULTS

Sample characteristics

Eight clinicians took part in the focus group: three consultants, three specialist respiratory trainee physicians (5–8 years post-qualification), an ILD respiratory nurse specialist and a specialist physiotherapist. The expert consensus group consisted of clinical academics (n=4), physicians (n=5), nurses (n=3), patients (n=4) and carers (n=2). Each lasted approximately 90 min.

Main findings

Two main themes were identified: clinical issues (table 1) and practical issues (table 2).

Clinical issues

Issues relating to the clinical interaction between patient and clinician could influence the willingness or ability of clinicians to use the tool. These were gaining better knowledge about patient and carer particularly in the ‘non-medical’ aspects; inadequate communication skills to assess psycho-social concerns and whether or not the NAT:ILD was beneficial for patients (table 1).

Practical issues

Facilitators that increased willingness to use the tool included (1) the tool being clear, concise and a consultation guide rather than a questionnaire or outcome measure, and (2) training to address skill gaps in holistic assessment (table 2).

Reflections from video recordings

There were few blocking body postures even when discussing barriers, reflecting the overall wish of participants to find solutions. The exception was when discussing time constraints of busy clinics; a sense of resignation or nihilism was shown by some participants until challenged and solutions proposed by others in the group.

DISCUSSION

The NAT:ILD was seen as a practical way to address the unidentified, unaddressed serious palliative and supportive care concerns of patients and carers. Participants identified gaps in clinical and communication skills, limited resources and need for culture change. Implementation challenges were delineated, but presented alongside potential solutions. The greatest concerns related to confidence and time constraints to assess psychosocial and spiritual need.

People with ILD have significant palliative and supportive care needs for which there are effective interventions. Despite this, palliative care access is rare; only 3% in a recent interstitial pulmonary fibrosis registry report.

Multidisciplinary care and excellent communication skills are the accepted service model for cancer services. Communication skills training delivers sustainable improvements in clinical practice but is not standard for respiratory clinicians unlike oncology and palliative teams in the UK.

Organisational and logistic factors were barriers to implementation. A change in service configuration to interdisciplinary clinics would be optimal. The NAT:ILD may provide a tool to support implementation of new practices into daily

care, catalyse service configuration change to a more patient-centric approach and facilitate multiprofessional working.

Strengths and limitations
Audio and visual recording helped interpretation of responses, particularly whether barriers were potentially surmountable.

As with all qualitative work, findings should be interpreted within the service context; this team liaised regularly with the palliative care breathlessness clinic. Other services may be less confident identifying symptoms without such support.

No clinician had used the NAT:ILD in practice. A subsequent dissemination workshop including clinicians with experience in practice upheld the findings (data available on request).

Implications for clinical practice
These clinicians were aware of the wider impact of ILD on patients and their carers. Discomfort assessing psychosocial and spiritual concerns stemmed from feeling (1) unsure what/how to ask and (2) ill-equipped to manage emerging problems. Training in assessment, a basic palliative approach and communication skills, and service reconfiguration with identification of referral pathways for specialist concerns is needed. A team relationship with palliative care services would be an initial step in multiprofessional education, training and support leading to a positive culture change.

CONCLUSION
Participants recognised that the NAT:ILD could help improve care of patients and carers, but were concerned about limited time and skills. Participants identified solutions including training in psychosocial/spiritual assessment and symptom management, support from other disciplines (palliative care and psychology) and MDT engagement and ways to overcome some barriers within resources. However, service development and additional resources may be required for optimal implementation of the NAT:ILD.
