Methods:

The inclusion criteria were: age ≥55 years and stable asthma and or COPD, with airflow obstruction defined by a pre-bronchodilator forced expiratory ratio (FER) <0.7 and Forced Expiratory Volume in 1 second (FEV₁) <80% predicted. Ability to attend study visits and satisfactory English language skills were needed. Exclusion criteria included: significant co-morbidities that the study may have impacted on, or an anticipated life expectancy of <3 months.

The study was conducted according to the International Conference on Harmonisation Good Clinical Practice Guidelines and was approved by the Hunter New England Ethics committee. The ACTRN registration number is 12611001278921.

Treatment allocation

Participants were allocated to either the MDAIM intervention or usual care control groups, using pre-determined criteria (the postcode of the participants’ residential address) and allocation was concealed from the referring and treating doctor.

Study Design

All eligible participants underwent a previously developed and tested single visit multidimensional assessment to measure clinical, functional, biological and psychosocial outcomes (Table 1).[1, 2] This assessment focused on the components of airway disease, co-morbidity, COPD self-management skills and risk factors (Table 1).

The intervention group participants were rescheduled for the following week, reviewed by the case manager and dietician and the care planning exercise was conducted. Subsequent visits were scheduled according to the treatment plan (table 1). The control group had their physician and pulmonary rehabilitation (PR) visits scheduled by their usual care treating team.

Participants were followed up at 3, 6 and 12 months for repeat multidimensional assessment. If the control participants had not yet completed their pulmonary rehabilitation programme (PRP) at 3
months, the study follow-up visit was postponed for a maximum of 4 weeks to enable completion of this aspect of usual care.

**Participant flow**

Thirty-six participants were recruited to the study and were randomised to the intervention (n=17) or the control (n=19) group (Figure 1). All participants in the intervention group and 17 in the control group completed the 3 month follow-up. There were 4 participants in MDAIM who experienced 5 adverse events that were secondary to the intervention treatment. Over 12 months there was 1 death in the MDAIM group and 2 in the control group. The cause of death in the intervention participant was cardiovascular disease, in the control group one participant died of respiratory failure and the other of renal failure.

**Intervention**

**MDAIM**

The intervention consisted of individualised management based on the baseline multidimensional assessment. A personalised care plan was developed by the study physician and case manager. The clinicians and participants agreed on the tailored interventions for each of the identified problems[3]. An inflammometry algorithm (Table 1 manuscript) was used to inform treatment decisions for airway inflammation, systemic inflammation, and mucus hypersecretion. Other tailored interventions were standardised according to best available evidence (Table 1).[1] The case manager coordinated the plan. The interventions were delivered over 3 months during individualised visits. PRP participation occurred concurrently.

**Control**

The control group received medical assessment, pharmacotherapy and ongoing management by a respiratory physician and referral to a PRP.

**Procedures**
QOL was assessed using the Saint George Respiratory questionnaire (SGRQ).[4] Airflow obstruction was assessed by spirometry (KoKo K313100 PDS Instrumentation, Louisville, CO, USA) to measure pre and post-bronchodilator FEV₁, FVC and FER according to ATS/ERS standards.[5] Predicted FEV₁ and FVC were calculated using NHANES III.[6]

Airway inflammation was assessed using induced sputum.[7] Lower respiratory sputum portions were selected from saliva, processed using dithiothreitol and differential cell counts obtained.[8]

Peripheral blood was collected for assessment of systemic inflammation, using high sensitivity C Reactive Protein (hs-CRP) analysed using the Siemens Healthcare Diagnostics (Marburg, Germany) ELISA. The analytical measurement range for this kit was 2.90 – 190mg/L.

Mucus hypersecretion was assessed using six items from the 1978 ATS/DLD Respiratory Symptom Questionnaire.[9] Participants reported on the presence, frequency, volume and colour of sputum expectorated. All other assessments are described in the online supplement and Table 1.

Analysis

Health status, measured by the SGRQ, was the primary outcome.[4] Secondary outcomes included: the number of problems detected using the multidimensional assessment, exacerbations, sputum cell counts and CRP. An intention to treat analysis was performed. All data were analysed using Stata 10 (Stata Corporation, College Station, Texas USA). Parametric results are reported as mean (CI) and non-parametric results as median (IQR). Parametric data analysis was performed using Students’ paired and non-paired t-tests as appropriate and the Chi square test for categorical data. Non-parametric analyses were performed using the two-sample Wilcoxon Rank Sum, the Kruskal-Wallis test for more than two groups, and Fisher’s exact test for categorical data. Poisson regression was used to analyse differences in hospitalisations between groups and the incident rate ratio (IRR) reported. Results were reported as significant when p<0.05.

Results

Number of clinical management problems

The intervention led to a statistically significant decrease in the number of clinical problems. The mean (CI) number at baseline was 10.2 (9-11.4) per participant for MDAIM. This was reduced to 6.4 (5-7.7); p=0.0001 after the intervention, which was also significantly fewer than the control group,
who post treatment had 10.3 (9.1-11.6) problems per participant (p= 0.0001). The mean change (reduction) in number of problems for the MDAIM was -3.8 (-5.3- -2.3) compared to 0.5 (-2.1-1.1); p=0.003 for the control group.

Lung Function

No differences were found between the groups in any of the lung function parameters.

Exacerbations

Over 12 months there were 46% (IRR=0.54; p=0.28) less admissions in the MDAIM group compared to control, however this did not reach statistical significance. Over 12 months there were fewer dropouts in the MDAIM; n=3 (17.6%) compared to control; n=8 (42%).

**Individualised interventions received by the MDAIM group**

**Inflammation based management**

The 5 participants with eosinophilic airway inflammation were all prescribed ICS at baseline. They received oral corticosteroids and the baseline median (IQR) sputum eosinophil % of 15.5 (7-15.7) decreased to 0 (0-4) (p=0.02) post intervention (Figure 1b manuscript). Sputum neutrophilia was detected in 6 (35.2%) participants. Targeted antibiotic therapy significantly improved and normalised sputum neutrophilia from a mean (CI) baseline sputum neutrophil % of 81.8 (72.1-91.5) to 55.8 (33.7-78.0) post intervention; p=0.02 (Figure 1c manuscript). CRP was >3mg/L in 11 (64.7%) of the MDAIM participants who were treated with simvastatin for 3 months. There was a significant reduction in CRP from a median (IQR) baseline of 9 (5-11) to 4 (1-5.3) mg/L post treatment; (p=0.02). To aid in mucociliary clearance, 11 participants with mucus hypersecretion received a positive expiratory pressure device with education and follow-up. Of these, 6 were also treated with nebulised hypertonic saline (6%, 10mL bd). At follow-up, mucus hypersecretion was present in only 4 of the 11 participants (p=0.04).
