ABSTRACT

This new guideline covers the rapidly advancing field of interventional bronchoscopy using flexible bronchoscopy. It includes the use of more complex diagnostic procedures such as endobronchial ultrasound, interventions for the relief of central airway obstruction due to malignancy and the recent development of endobronchial therapies for chronic obstructive pulmonary disease and asthma. The guideline aims to help all those who undertake flexible bronchoscopy to understand more about this important area. It also aims to inform respiratory physicians and other specialists dealing with lung cancer of the procedures possible in the management and palliation of central airway obstruction. The guideline covers transbronchial needle aspiration and endobronchial ultrasound-guided transbronchial needle aspiration, electrocautery/diathermy, argon plasma coagulation and thermal laser, cryotherapy, cryoextraction, photodynamic therapy, brachytherapy, tracheobronchial stenting, electromagnetic navigation bronchoscopy, endobronchial valves for emphysema and bronchial thermoplasty for asthma.

This guideline is based on the best available evidence. The methodology used to write the guideline adheres strictly to the criteria as set by the Appraisal of Guidelines Research and Evaluation (AGREE) collaboration <http://www.agree-collaboration.org/1/agreeguide/>. Three hundred and eighty-seven papers were critically appraised using the Scottish Intercollegiate Guidelines Network (SIGN) critical appraisal checklists. A web-based guideline development tool (<http://www.bronchoscopy-guideline.org/>) enabled each pair of reviewers to collaborate online. The reliability of the evidence in each individual study was graded using the SIGN critical appraisal checklist. The body of evidence for each recommendation was summarised into evidence tables, formulated into evidence statements and graded using the SIGN grading system into recommendations.

DIAGNOSTIC TECHNIQUES

Conventional transbronchial needle aspiration

Conventional transbronchial needle aspiration (TBNA) is a safe and simple procedure mainly used to sample hilar and mediastinal lymph nodes in cases of suspected malignant involvement or

sarcoidosis (Evidence level 2++). It should be used at the time of initial bronchoscopy to sample lymphadenopathy noted on CT scanning. The guideline includes a step-by-step guide for performing conventional TBNA.

Endobronchial ultrasound-guided transbronchial needle aspiration

Endobronchial ultrasound transbronchial needle aspiration (EBUS TBNA) has high sensitivity and specificity for identifying malignancy in mediastinal and hilar lymph nodes in patients with lung cancer (Evidence level 2++), and also has a high sensitivity for identifying malignancy when used for sampling paratracheal and peribronchial parenchymal lung masses (Evidence level 3). In cases where EBUS-TBNA results are negative for malignancy, a confirmatory surgical biopsy should be performed. EBUS-TBNA also has high sensitivity for identifying non-caseating granulomas in hilar and mediastinal lymph nodes in cases of suspected sarcoidosis (Evidence level 2++).

THERAPEUTIC TECHNIQUES

Debulking techniques

There are a number of effective debulking techniques for the removal of endobronchial tumour; the treatment of choice will depend largely on cost and availability. Rigid bronchoscopy techniques have advantages in terms of airway control, the ability to easily remove a large volume of tumour, to dilate the airway and to deploy silicone stents. In the UK there are, however, relatively few experienced practitioners in rigid bronchoscopy outside surgical units. This guideline therefore covers the use of interventional techniques which utilise the more widely available flexible bronchoscopy.

In patients with intrinsic central airway obstruction, with or without critical airway narrowing, immediate debulking using endobronchial diathermy, argon plasma coagulation, cryoextraction and thermal laser may all be considered (Evidence level 3). Brachytherapy, conventional cryotherapy and photodynamic therapy (PDT) may also be considered for debulking if there is time for their delayed effect to take place. These techniques are not generally useful for extrinsic compression. Endobronchial diathermy, argon plasma coagulation and cryoextraction are all relatively safe, simple and are much cheaper than laser, brachytherapy and PDT.

Table 1 Summary of the effectiveness of endobronchial debulking techniques

	Effectiveness in palliating symptoms (% patients)	Effectiveness to open airway (% patients)
PDT	100% ¹	80% ²
Brachytherapy	69–90% ^{1 3 4}	78–85% ^{1 3 4}
Cryotherapy	70–93% ^{1 5–7}	77–79% ^{1 5–7}
Cryoextraction	>90% ⁸	83–91% ⁸
Laser	63–94% ^{9–11}	>90% in trachea ² 60–70% for more distal lesions ^{2 9–11}
Diathermy	70–97% ^{11–13}	88% ^{11–13}
APC	100% of haemoptysis ¹⁴	91% ^{1 14}

APC, argon plasma coagulation; PDT, photodynamic therapy.

These techniques are effective in alleviating symptoms of breathlessness and haemoptysis in patients with endobronchial malignancy (see table 1).

Treatment of early lung cancer

Many of these debulking techniques, including endobronchial diathermy, cryoextraction, brachytherapy and PDT, may also be used for the treatment of early central lung cancer with curative intent and for treating localised endobronchial disease in patients unfit for surgery or other radical therapy.

Stents

Following tumour debulking, self-expanding metal stents can effectively maintain airway patency and are also effective in the treatment of extrinsic compression (Evidence level 3). Non-removable stents should be used with caution, if at all, in non-malignant disease due to the potential for stent fracture and other long-term complications.

EMERGING APPLICATIONS FOR FLEXIBLE BRONCHOSCOPY

There are a number of recent diagnostic and therapeutic applications using the flexible bronchoscope which have not yet established a clear place in routine practice. These include electromagnetic navigation bronchoscopy, treatment of emphysema by lung volume reduction using valves and bronchial thermoplasty for asthma.

Electromagnetic navigation bronchoscopy

The use of electromagnetic navigation bronchoscopy to locate tumour not visible under direct vision using three-dimensional data from a CT scan has been shown to yield a diagnostic rate of between 59% and 80%, with greater accuracy for lesions >40 mm in diameter. It is a safe, effective but currently expensive modality for sampling peripheral lesions, and studies using virtual bronchoscopy alone have similar diagnostic rates.

Endobronchial valves

Endobronchial valves may be used in the treatment of emphysema with severe hyperinflation, in an attempt to reduce lung volume. The valves are inserted into the target area via flexible bronchoscopy under conscious sedation or general anaesthesia. In patients with severe emphysema and hyperinflation they

have been shown to produce small improvements in lung function (Evidence level 2–). Sufficient efficacy has not yet been demonstrated to recommend their routine use.

Bronchial thermoplasty for asthma

Airway smooth muscle may also have a role in the pathogenesis of asthma by secreting proinflammatory cytokines and promoting airway remodelling. The goal of bronchial thermoplasty is to reduce airway smooth muscle by the application of radiofrequency-generated heat at 65°C. Although there is a high level of evidence for the effectiveness of this technique in reducing symptoms, adverse events and frequency of exacerbations (Evidence level 1), its place in the treatment of asthma remains to be established and we recommend that treatment should be limited to a few specialist centres in carefully selected patients.

AUDIT, RESEARCH, TRAINING AND STANDARDS OF CARE

The guideline provides audit, research and training recommendations, and also indicates recommended standards of care.

Competing interests None. A declaration of interest is available in Appendix 1 of the guideline.

Provenance and peer review Not commissioned; internal and external peer review undertaken by the Standards of Care Committee of the British Thoracic Society.
