LETTERS TO THE EDITOR

BCG vaccination by multipuncture method

I write in response to the article by Al Jarad et al. on this topic. The first study to compare the efficacy of BCG vaccination and its side effects using the Bignal multipuncture device with the reusable handle and disposable heads was the pilot study of neonatal BCG vaccination carried out in 1992 for the Department of Health in our health authority.1

In previous studies in neonates and children under two, referenced in the paper by Al Jarad et al., an 18–20 needle percutaneous head gave approximately the same degree of tuberculin conversion as did intradermal vaccination, but to achieve this in older children and adults, 36–40 punctures were required. This would require either a 40 needle head, a double vaccination with two 18–20 needles. This is why percutaneous BCG is currently only licensed for children aged under two years. Although in neonates1 and in Al Jarad’s study1 in older children the rate of tuberculin conversion was lower with percutaneous than with intradermal vaccination, tuberculin conversion does not necessarily equate to lower efficacy. In the early studies on Al Jarad’s device the protective efficacy of the vaccination was related to the presence of a scar after vaccination, but not to the tuberculin test result after vaccination. Those with a BCG scar but a negative post vaccination tuberculin test—that is, no tuberculin conversion—had the same degree of protection against tuberculosis over the 15 years following vaccination as did those with a scar and a positive post vaccination tuberculin test.1

The multipuncture method is undoubtedly easier to use in neonates because their very thin skin makes intradermal vaccination difficult, and also in nervous teenagers. Further long term studies on large numbers of subjects would be required to determine whether the technique using only 18 needles in older children is as effective as intradermal vaccination. Such studies may well prove to be unnecessary. The PHSLS system for enhanced tuberculosis surveillance begun this year should, with sufficient cooperation, be able to give the relevant information by the end of 2001 to show whether England and Wales meet the internationally recommended criteria for discontinuation of unselective BCG vaccination in low prevalence countries.1 BCG vaccination of selective at risk groups, however, could still be required.

nity conferred by effective BCGs and whole bacillus vaccines in relation to individual varia-
tion in induced tuberculin sensitivity and to technical variations in the vaccines. Tuber-

AUTHORS’ REPLY To our knowledge our study1 was the first to compare the Bignal device with the conventional device in the multipuncture technique in schoolchildren. We were interested in assessing its efficacy in this particular group as we felt that the multipuncture technique would allow us to protect more schoolchildren in a part of London where it is difficult to access this population. The studies by Cundall et al.12 and later by Ormerod and Palmer13 made the same comparison in neonates and small children.

We agree (and stated) that the 18 needle device may not be sufficient to convey a similar conversion rate of the tuberculin test. The manufacturers were unable to produce 40 needle heads as they would require an unacceptable high pressure on the handle to release the needles. We felt that applying two successive punctures with an 18 needle head on the same skin area would not be practicable as the head comes off and would need to be changed after each application. In addition, schoolchildren (and the operators) would not appreciate two applications.

Dr Ormerod’s statement on the BCG scar being a predictor of protection may be inappropriate for the intradermal method. In our study the BCG scar in children who received the multipuncture method was not visible in under five children.

Dr Ormerod is in agreement with our statement that the conversion of the tuberculin test does not equate to protection from tuberculosis, but is frequently used as an indirect measure of the efficacy of BCG vaccination.

We strongly support the PHLS system for enhanced tuberculosis surveillance in the UK, but unfortunately we do not hold out Dr Ormerod’s optimism that it will indicate that unselective BCG vaccination can be discontinued in boroughs and countries where notification rates of tuberculosis are high. Further studies on the protective values of multipuncture BCG may still be appropriate.

Respiratory care units for non-invasive mechanical ventilation in motor neurone disease

We read with interest the review by Polkey et al. pointing out the need to use all means possible to enable patients with motor neurone disease to achieve the best quality of life.

The authors state that, in order to maintain 24 hour ventilatory support, nasal ventilation must be complemented with alternative strategies during the day that are not suitable for widespread use in district general hospitals. We consider that it is possible to maintain 24 hour non-invasive ventilation in patients with motor neurone disease if nasal ventilation is combined with other non-invasive techniques such as mouthpiece ventilation or a pneumobelt, and with manual or mechanical expiratory muscle aids to clear secretions in those patients whose weakness makes spontaneous coughing ineffective.1 It is important to provide this care centrally because they can delay tracheostomy and additional problems in most patients with motor neurone disease and are the only way for those patients who reject tracheostomy but need ventilatory support. However, we are in agreement with Polkey et al. that this treatment must be performed by trained staff in respiratory care units. Moreover, these units are the best place to prevent respiratory morbidity and mortality, to enhance cooperation between patients, relatives and caregivers, and to manage clinical and psychological problems during the terminal phase of the disease.

In our experience the care of patients with motor neurone disease outside respiratory care units needs to be improved. These patients must not be negatively discriminated against compared with other chronic patients receiving even more expensive but socially accepted treatment. We must therefore try to ensure that all patients with motor neurone disease have access to management in a respiratory care unit in order to receive standardised quality care both in hospital and at home.

1 Polkey M, Lyll R, Davidson A, et al. Ethical and clinical issues in the use of home non-invasive mechanical ventilation for the palliation of breathlessness in motor neurone disease. Tho-

AUTHOR’S REPLY We thank Dr Servera and colleagues for their interest in our paper. We agree that patients with motor neurone disease should have access to specialist expertise where this is necessary. However, we are also conscious that travel can be diffi-
cult for some patients with advanced disease and our experience is that, in many cases, satisf-
factory palliation can be achieved using non-invasive positive pressure ventilation alone. This treatment could theoretically be
Asthma deaths in Scotland and in Wales

It is surprising to say the least that, although both of district hospitals and specialist services, as well as promoting patient self-management to minimise the occurrence of such episodes.

AUTHORS’ REPLY We are aware of the work to which Dr Grant refers, and agree that self-admission schemes can prevent asthma deaths by avoiding the delays that sometimes occur with conventional admission procedures. Different versions of self-admission schemes operate throughout Wales, but there is no uniform practice and it is possible that a few deaths in our series might have been prevented had such a scheme operated everywhere. However, in most cases it is unlikely that the outcome would have been different, particularly when patients failed to take their illness seriously, were not under the care of a respiratory physician, or had no prior history of severe attacks.

Nebulised fluticasone

The place of nebulised inhaled corticosteroids in the treatment of patients with asthma is difficult to assess, but Dr J M Hill’s editorial in Thorax was inaccurate and bel攻击 accepted standards for a major medical journal.

provided by an interested chest physician working in a district general hospital. We recognise that, in practice, it may be difficult to identify the necessary resources and that, conversely, an under-resourced service may lead to suboptimal care; however, this is true both of district hospitals and specialist centres.

M POLKEY
Lanefox Unit, St Thomas’ Hospital, London SE1 7EH, UK

AUTHORS’ REPLY Dr Grant’s comments are welcome and highlight the importance of including all the information obtained in a study such as SCIAD in a paper of suitable length for publication. The sudden deterioration of previously well patients, so called “brittle asthma”, was not a major feature of the deaths studied, raising the possibility that there may be relatively fewer such patients or that patients who die suddenly in the community, even with a history of asthma, are correct. With other causes of death, it is noteworthy that the routine management of patients studied, including the use of inhaled steroids, was appropriate in the majority of cases, so it may be that such a general improvement in standards of asthma care, there are fewer patients with brittle disease than there were previously. Review of the cases where delays were cited as a factor showed not a case where delay was the only factor in patients in whom a sudden onset of symptoms was reported; poor compliance was also commented on in these few patients. A review of the cases where death occurred in A&E likewise revealed no case of sudden deterioration (within hours) definitely due to sudden onset of severe asthma; in most cases a number of other factors including aspiration of vomit and the use of non-prescribed drugs was a factor. There is therefore no evidence of deaths which would have been prevented by fast track admission and, with the more widespread administration of oxygen and nebulised bronchodilators to paramedical ambulance crews, there are other reasons for emphasising the use of normal referral services, as well as promoting patient self-management to minimise the occurrence of such episodes.

Nebulised fluticasone is frequently referred to, yet all the studies referenced have only been published as abstracts (sponsored by the manufacturers of fluticasone) in supplements to journals. There are insufficient details for these papers to be properly scrutinised. They have not been subject to proper peer review and should have no place as the sole references for a new treatment for asthma in the editorial of a major medical journal.

Dr Hill states that “it is clear from a number of studies that fluticasone is twice as potent as budesonide at a mg for mg dose” but references this with a study which compares fluticasone with beclometasone and not budesonide. This is clearly incorrect. She forgets that different inhaling devices influence potency ratios. Thus, fluticasone in a Diskhaler may be equipotent with budesonide in a Turbohaler and not budesonide.

As far as nebulised steroids are concerned, she seems unaware that different nebuliser systems may affect the amount delivered to the lung by a factor of four or more. Is this not important to mention? Also, the respirable fraction of nebulised steroid depends on the physical properties of the steroid molecule. For example, beclometasone might be equipotent with budesonide in metered dose inhalers, but beclometasone solution nebulises poorly and has been withdrawn from use. So, what is the potency ratio between nebulised fluticasone and budesonide? The answer is unknown, simply because there are no comparative studies. Yet Dr Hill confidently assumes a 1:2 potency ratio when giving the costs of each treatment—and fluticasone appears to be one half the price of budesonide.

Finally, any article, editorial or otherwise—and especially one that makes unfavourable comparisons between drugs—should be accompanied by a declaration of competing interests. There is nothing wrong with having a competing interest but everyone should know. Dr Hill should have stated these interests (if any) in the same detail as reported recently in a review article on asthma drugs in the BMJ.

Conflict of interests: neither Dr Todd nor his spouse has shares in any pharmaceutical company. He has received payment from Astra, Boehringer, 3M, Forest Laboratories (USA), Glaxo/Wellcome, MSD and Zeneca for presentations/lectures in the past five years. He has only received payment for research from GlaxoWellcome (fluticasone).

**AUTHOR’S REPLY** The author thanks Dr Todd for his constructive comments on her review article.1 There are few published randomised controlled trials of nebulised fluticasone or budesonide in the treatment of asthma. Despite this, these agents are being actively marketed by the pharmaceutical industry so it is vital that the debate about the place of these agents in the treatment of asthma should continue. Finally, the author therefore thinks it is justifiable to review what evidence is available, accepting its limitations in abstract form.

The author apologises for incorrectly quoting a paper comparing the potency of budesonide and fluticasone. The correct reference is cited below. However, the author had presumed that the readers of *Thorax* would be well aware that data comparing different inhaled corticosteroids apply only to the type of inhaler used in any comparison, and that this basic principle did not require explanation.

Dr Todd’s comments about different neb- uliser systems and drug solubility are well taken. However, this was a short review of the available clinical evidence for the use of nebu- lised corticosteroids in the treatment of patients with asthma. It was not possible to, nor did I, review nebuliser pharmaceuticak and, as Dr Todd states, there are no comparative studies of the potency ratio of nebulised budesonide and fluticasone.

Dr Todd and Dr Hill nor her spouse has shares in any pharmaceutical company manufacturing asthma treatments. She has received payment from GlaxoWellcome, Boehringer, Bayer, Abbott Laboratories and Astra for presentations/lectures and for attending meetings in the last three years.

**Pyoderma gangrenosum**

Wang et al report an interesting case of systemic pyoderma gangrenosum (PG) with associated lung injury.1 They recognise the importance of excluding Wegener’s granulomato- 

osis (WG) in patients with respiratory symptoms and cutaneous ulceration, but in their case seem only to have done this on clinical and histopathological grounds. A more complete assessment should include testing for cANCA and anti-proteinase 3 (PR3).2

We are currently treating a 54 year old ex-smoker who presented for investigation of haemoptysis and who subsequently devel- oped epidermolysis and skin lesions resembling PG. Initial investigations were Hb 11.5 g/dl, WBC 9.4 × 109/l, platelets 401 × 109/l, ESR 86 mm/h, and CRP 181 mg/l. Renal function was normal. The chest radiograph showed alveolar shadowing in the lower left zone and an HRCT scan confirmed pulmonary infiltrates. Fibreoptic bronchoscopy and trans- bronchial biopsy specimens were normal. Skin biopsy specimens showed epithelial cell necrosis and acute inflammatory changes with no evidence of vasculitis or granulomas, consistent with PG. The ANCA assay was positive with a cytoplasmic distribution and was directed against the proteinase 3 epitope. Despite the absence of histological evidence, the clinical features and positive ANCA supported a diagnosis of PG. One month into treatment with pulsed intravenous methyl- 

prednisolone and cyclophosphamide the patient is clinically better with resolution of haemoptysis, healing of the pyoderma-like lesions, and a fall in the CRP (from 21 mg/l).

Patients with WG frequently present with non-specific signs and symptoms and a high index of suspicion is important.3 This case highlights the importance of testing for ANCA in patients with PG and respiratory tract symptoms as the treatment of WG requires prolonged immunosuppression for at least a year. Whilst PG itself may be associ- 

ated with pANCA, the presence of cANCA directed against PR3 is highly suggestive of WG. The histological features of WG are often patchy in distribution and the absence of the characteristic findings of vasculitis, granulomas, and necrosis does not exclude the diagnosis.4

3 Langford CA, Hoffman GS. Wegener’s granulo- 

**AUTHOR’S REPLY** I would like to thank Dr Perkins and colleagues for their interest in our article and for their suggestions. The ANCA assay was only introduced in our hospital in 1999 so we could not use this method to dis- 

tinguish between WG and PG before that time. The diagnosis of WG in our hospital depends mainly on histopathological exam- 

ination. In September 1999 the patient came for re-examination. All drugs had been stopped for more than four months, she had no symptoms, and all investigations (including chest radiograph, ESR, and CRP) were normal.

Hoffman et al reported the treatment outcome of 158 patients with WG.1 One hundred and thirty three patients received standard treatment of daily low dose cyclo- 

phosphamide (2 mg/kg/day) plus prednisone (1 mg/kg/day). This protocol produced marked improvement or partial remission in 91% of recipients; 75% experienced com- 

plete remission with a median time of 12 months. Less than 10% of patients so treated experienced remission as late as six years after beginning the protocol. However, 10 cases received corticosteroid only. In this group only two of six cases with limited WG (with- 

out renal injury) achieved sustained remis- 

sion. The authors concluded that the course of WG had been dramatically improved by daily treatment with cyclophosphamide and a corticosteroid; other treatment regimens had not achieved such high rates of remission and successful maintenance.

Compared with Hoffman’s standard proto- 

col, the dosage of cyclophosphamide and du- 

ration of treatment in our patient were lower and shorter, respectively. We feel it is unlikely that the clinical picture would have improved so significantly within 10 days if the diagnosis was WG. Of course, the best way is to perform an ANCA test and we intend to do so.

1 Hoffman GS, et al. Wegener’s granulomato- 

**Therapeutic equivalence of inhaled salbutamol**

The meta-analysis by Hughes et al was hindered by difficulties in comparing trials that were often flawed and of varied design.1 The authors correctly pointed out that, in most of the studies, the use of equivalence as the null hypothesis was invalid. In addition, all but two of the studies looked at the bronchodilator effects in the presence of basal airway tone, when the top of the dose response curve for bronchodilator response occurs in mild to moderate asthma at a sal- 

butamol dose of approximately 200 µg for chlorofluorocarbon (CFC) or hydrofluor- 

alkane (HFA) pressurised metered dose inhalers (pMDIs).2 To construct a proper dose response curve to estimate relative broncho- 

dilator potency would therefore necessitate the use of doses much lower than 200 µg or evaluation of patients with more severe asthma. Two of the cited studies evaluated functional antagonism against histamine in- 

duced bronchoconstriction in patients with mild to moderate asthma. However, in such patients the dose response curve for bronchodilator protection is relatively shallow. For example, in a recent study of 72 patients with mild to moderate asthma a fourfold increment in the dose of formoterol Turbohaler (from 6 µg to 24 µg) only resulted in a shift in methacholine hyperresponsiveness of one doubling dose.3

One simple way of evaluating bioequivalent doses of inhaled salbutamol is to evaluate the relative respirable lung dose, which can be quantified as lung bioavailability. This is defined as the early lung absorption profile in the first 20 minutes after inhalation, expressed as the maximal plasma concentration ($C_{max}$) for the samonidal dose.

We have therefore reviewed eight studies performed in our laboratory using an identi- 

cal design in which a nominal dose of 1200 µg salbutamol was administered via different devices in healthy volunteers. Where the same device was evaluated in two or more
studies, the highest value for C_{max} was used. A significant difference in lung bioavailability between Nebuhaler spacer with HFA-pMDI (C_{max} = 2.52 ng/ml), the lung dose is similar to the adjusted device will remain the same and is related to the bronchodilator response. Measurement of the lung bioavailability of salbutamol in healthy subjects may therefore represent a simple in vivo method for preliminary quantification of the relative lung dose from different inhaler devices to select rational doses for subsequent clinical equivalence studies in asthmatic patients.
