Bcl-2 expression in sputum eosinophils in patients with acute asthma

An-Soo Jang, Inseon-S Choi, Soong Lee, Jeong-Pyeong Seo, Seung-Won Yang, Chang-So. Park

Abstract

Background—Eosinophils play a pivotal role in asthmatic airway inflammation. Apoptosis is thought to be critically relevant in promoting the clearance of inflammatory cells and the resolution of inflammation. Bcl-2 inhibits apoptosis in cellular systems. A study was undertaken to determine whether bcl-2 expression in sputum reflects the clinical severity of patients with asthma. The relationship between bcl-2 expression in sputum eosinophils and eosinophil activation markers such as interleukin (IL)-5 and eosinophil cationic protein (ECP) levels in sputum supernatant was evaluated.

Methods—Sputum was obtained from 18 patients with asthma. Fresh expectorated sputum separated from saliva was treated with an equal volume of dithiothreitol 0.1%, cytospun for cell differentials and bcl-2 stains, and the supernatant was collected for biochemical assay. Bcl-2+ eosinophils were stained using immunocytochemistry, ECP was measured by fluoroimmunoassay, and IL-5 was detected by sandwich enzyme linked immunosorbant assay.

Results—Twelve patients with severe or life threatening asthma had more bcl-2+ eosinophils (mean difference 46.8% (95% CI 27.0 to 66.6), p<0.01) and a higher ECP level (p<0.01) in the sputum than those with mild to moderate asthma (n = 6). IL-5 was frequently detected in patients with severe or life threatening asthma (11/12 versus 1/6, p<0.01). There was a significant positive correlation between bcl-2+ eosinophils and ECP levels (r = 0.61, p<0.01) and between bcl-2+ eosinophils and IL-5 levels (r = 0.83, p<0.01). There was a significant negative correlation between bcl-2+ eosinophils and FEV₁/FVC (r = −0.54, p<0.05).

Conclusion—The increased expression of bcl-2 in eosinophils from sputum of subjects with severe asthma suggests that bcl-2 may prolong survival and decrease apoptosis of airway eosinophils in asthma.

Keywords: eosinophils; apoptosis; asthma; sputum; bcl-2

Eosinophils are known to play a pivotal role in asthmatic airway inflammation. Infiltration of eosinophils into the bronchial wall and respiratory epithelial damage are two distinctive features of asthma.1 These bronchial changes involve four steps—namely, enhanced eosinophil production, recruitment of lung tissue, activation of eosinophils, and release of mediators.

The prolongation of eosinophil survival is important in the pathogenesis of asthmatic airway inflammation. Apoptosis plays a central part in normal tissue homeostasis as well as having a role in various clinical diseases characterised by either increased or decreased cell survival.2 It is thought to be critically important in promoting the clearance of inflammatory cells and the resolution of inflammation. Apoptosis of eosinophils may be clinically relevant in asthma, promoting the removal of airway eosinophils and contributing to clinical improvement. Among apoptosis suppressing genes, bcl-2 prevents apoptosis either through altering cell cycle rates or by activating antioxidant associated mechanisms.3

Interleukin (IL)-5, a cytokine that attracts, activates, and prolongs the survival of eosinophils, is important in causing eosinophilic inflammation in the asthmatic airway and contributing to eosinophil viability in the sputum of asthmatic patients during attacks.4 It inhibits eosinophil apoptosis by upregulation of bcl-2.5

Vignola et al6 reported that bcl-2+ cells in bronchial biopsy specimens from patients with asthma were higher than those from control subjects and from subjects with chronic bronchitis; the number of bcl-2+ cells correlated with the severity of the disease. Skin biopsy specimens from patients with hyper-eosinophilic syndrome have also been reported to express bcl-2 protein.7

This study was undertaken to determine whether bcl-2 expression in sputum reflects the clinical severity of patients with asthma. The relationship between bcl-2 expression in sputum eosinophils and eosinophil activation markers such as IL-5 and eosinophil cationic protein (ECP) in sputum supernatant was evaluated.

Methods

SUBJECTS

Eighteen patients with asthma were recruited from the Division of Allergy, Department of Internal Medicine, Seonam University and Chonnam University Hospital between February and August 1999. The diagnosis of asthma had been previously established in 13 patients by their symptoms of recurrent episodic wheezing, cough, and/or dyspnoea, and either by methacholine airway hyperresponsiveness in...
Bcl-2 in asthmatic sputum eosinophils

The total number of pluses was added. Atopy follows: 0 = no diagnosis, 1–2 mm larger than control, ++ = 3–5 mm using 55 common allergen extracts. The wheal units. Allergy skin prick tests were performed using DiQuick (Kookje Scientific Products, Tokyo, Japan). Two coded cytopsins were prepared at 400 rpm for five minutes. One slide was air dried and stained with Trypan blue stain (GibcoBRL, Grand Island, NewYork, USA) and two others were stained with Diff-Quick (KoosteScientificProducts, Tokyo, Japan). Another two slides prepared for immunocytochemical analysis were air dried for 10 minutes, fixed in 0.25% formalin for five minutes at 4°C, wrapped in pairs in foil and stored at –70°C. Cell differential counts of 400 non-squamous cells were performed on Diff-Quick stained slides by two investigators who did not know the subject’s clinical history, and the results were expressed as a percentage of the total non-squamous cell count.

IMMUNOCYTOCHEMICAL ANALYSIS OF BCL-2

Bcl-2 in asthmatic sputum eosinophils

10 patients or by an improvement of 15% after salbutamol 200 µg (when the forced expiratory volume in one second (FEV1) was <75% predicted) in three patients. In the five remaining patients the diagnosis was confirmed by an improvement in the FEV1 (15%) following anti-asthma therapy. No subject had respiratory infection for four weeks before the study. Seonam University Hospital Research Committee approved the study and all subjects signed the informed consent forms.

STUDY DESIGN

Eosinophils and eosinophil activation markers in sputum were measured in asthmatic patients. A questionnaire on symptoms and medications was given to all patients and a spirometric test was performed. Sputum was then collected and skin prick tests and a methacholine provocation test were performed. The clinical severity of asthma was classified according to the International Consensus Report. Asthma exacerbations were classified according to the International Consensus Report.10 Asthma exacerbations were graded by symptoms (breathlessness, talking, and alertness), signs (respiratory rate, use of accessory muscles, wheeze, pulse/min, and pulsus paradoxus), and functional assessment (peak expiratory flow rate, arterial blood gas analysis). A person blinded to the clinical characteristics of the subjects performed the sputum measurements.

Spirometric tests were performed according to the American Thoracic Society standards using a SensorMedics 2200 spirometer (Cardiopulmonary Care Company, California, USA). The representative values for forced vital capacity (FVC) and forced expiratory volume in one second (FEV1) were selected according to the Intermountain Thoracic Society criteria11 and the reference values were taken from the reports by Choi11 with some modifications. Methacholine challenge tests were carried out using a modification of the method described by Chai et al12 and the results were expressed as PC20 in non-cumulative units. Allergy skin prick tests were performed using 55 common allergen extracts. The wheal size was recorded at 15 minutes and scored as follows: 0 = no difference from control, + = 1–2 mm larger than control, ++ = 3–5 mm larger than control, +++ = 6–8 mm larger than control, ++++ = >8 mm larger than control. The total number of pluses was added. Atopy was defined as an atopy score of >1.4.

SPUTUM INDUCTION AND PROCESSING

Sputum was induced only when it could not be produced spontaneously. The sputum induction was performed as a modification of the method described by Fahy et al.13 All subjects were premedicated with two puffs of inhaled salbutamol (200 µg). Subjects inhaled 3% hypertonic saline solution aerosols generated by an ultrasonic nebuliser (NE-U03, OMRON Co, Tokyo, Japan) with a maximum output of 0.15–0.3 ml/min and a mass median aerodynamic diameter of 4.5 µm. Hypertonic saline was inhaled for 15–20 minutes according to the severity of the asthma until an adequate volume of sputum was expectorated. Subjects were asked to rinse their mouth and blow their nose to minimise contamination with saliva and postnasal drip. They were encouraged to cough deeply and frequently during hypertonic saline inhalation. They were instructed to cough the sputum into a sterile plastic container. The sample volumes and duration of sputum induction were recorded. FEV1 was measured before, during, and after induction of sputum. Sputum induction was stopped if the FEV1 fell by ≥15%.

The appearance of the sputum was recorded as mucoid, mucopurulent, or purulent. Sputum was selected from saliva and processed within two hours. The method of sputum examination described by Popov et al was modified.14 Sputum was treated by adding equal volumes of 0.1% dithiothreitol (Sputalysin 10%; Gibco BRL, Grand Island, New York, USA) followed by equal volumes of Dulbecco’s phosphate buffered saline (D-PBS). The sample was then mixed gently and placed in a shaking water bath at 37°C for 15 minutes to ensure complete homogenisation. The sample was removed from the water bath periodically for further brief gentle mixing. The suspension was filtered through gauze (1 mm pore size), the filtrate was centrifuged at 1500 rpm for 10 minutes, and the supernatant was aspirated and stored in Eppendorf tubes at –70°C for later assay. The cell pellet was resuspended in 1000 µl D-PBS and the total number of non-squamous cells was counted in a modified Neubauer haemocytometer. The cell suspension was adjusted to 0.5 × 10⁵/ml and then 50 µl of cell suspension was placed in a Sakura cytocentrifuge (Model CF-127, Tokyo, Japan). Two coded cytopsins were prepared at 600 rpm for five minutes. One slide was air dried and stained with Trypan blue stain (GibcoBRL, Grand Island, New York, USA) and two others were stained with Diff-Quick (KoosteScientificProducts, Tokyo, Japan). Another two slides prepared for immunocytochemical analysis were air dried for 10 minutes, fixed in 0.25% formalin for five minutes at 4°C, wrapped in pairs in foil and stored at –70°C. Cell differential counts of 400 non-squamous cells were performed on Diff-Quick stained slides by two investigators who did not know the subject’s clinical history, and the results were expressed as a percentage of the total non-squamous cell count.

IMMUNOCYTOCHEMICAL ANALYSIS OF BCL-2

Immunocytochemical analysis was performed on sputum cytopsin slides with Probe On Plus slide (FisherScientific, Pittsburgh, Pennsylvania, USA). All steps in the staining procedure were done at 50°C in a Microprobe system taking advantage of capillary gap action15 produced by two approximated Probe On Plus slides. The primary antibody was applied for 15 minutes with anti bcl-2 antibody (Dako, Copenhagen, Denmark). Antigen/antibody complexes were detected with a goat anti-mouse IgG (Sigma, StLouis, Missouri, USA) for 10 minutes followed by avidine alkaline phosphatase (Dako)16 for seven minutes after blocking endogenous alkaline phosphatase.
activity in Redusol (Biomeda, Foster City, California, USA) for two minutes. The chromogen reaction consisted of Fast Red TR Salt (Research Genetics, Huntsville, Alabama, USA) for 10 minutes followed by 30 seconds of haematoxylin. Bcl-2 antibodies were diluted in primary antibody diluent (Research Genetics) at the final concentration of 5 µg/ml. Positive controls for bcl-2 consisted of known positive samples of human spleen included with each staining reaction. Negative controls consisted of staining without the primary antibody. All slides were examined using standard light microscopy by two observers and scored as percentage of positive eosinophils over total eosinophils. The intensity of the staining reaction was not quantified. The results were expressed as percentage of positively stained cells over total eosinophils.

ECP AND IL-5 MEASUREMENT
The concentration of ECP in 400 µl thawed supernatant was determined by fluoroimmunoassay (UniCAP system, Pharmacia AB, Uppsala, Sweden). IL-5 was measured by quantitative sandwich enzyme immunoassay (Quantikine; R&D System Inc). Samples were analysed in duplicates. The limits of detection for the ECP and IL-5 assays were 2.0 µg/l and 3 pg/ml, respectively.

DIFFERENTIAL SPUTUM COUNTS
Eighteen sputum samples from asthmatic patients were analysed. The sputum had less than 30% squamous epithelial cells and more than 85% cell viability. The proportion of eosinophils was significantly higher in patients with severe or life threatening asthma than in those with mild to moderate asthma (49.8 (6.5)% versus 10.3 (4.1)%, p<0.01), whereas the proportion of macrophages was lower (26.4 (5.5)% versus 59.5 (11.8)%, p<0.01). No significant differences were noted between the two groups of patients in either total cell count (8.1 (3.4) × 10⁵/ml versus 5.0 (0.9) × 10⁵/ml) or the absolute or relative numbers of lymphocytes and epithelial cells.

STATISTICAL ANALYSIS
All data were analysed using the SPSS version 7.5 for Windows. Data are expressed as mean (SE). Inter-group comparisons were assessed by a non-parametric method using the Mann-Whitney U test. The correlation between variables was examined by Spearman rank correlation coefficient. A p value of less than 5% was regarded as statistically significant.

RESULTS
The characteristics of the study subjects are shown in table 1. Patients with severe to life threatening asthma had significantly lower FEV1 and FEV1/FVC than those with mild to moderate persistent asthma.

Bcl-2 in asthmatic sputum eosinophils

Discussion

Inhibition of eosinophil apoptosis may play an important role in chronic airway inflammation. In this study we found that anti-apoptotic bcl-2 protein was increased in patients with severe asthma compared with those with mild asthma. The evaluation of bcl-2 expression in sputum eosinophils may be a useful marker for monitoring airway inflammation in asthma.

Asthma results from complex interactions between inflammatory cells, mediators, and the cells and tissues of the airways. Eosinophils are known to play a major part in asthmatic airway inflammation. They are cells of granulocyte lineage formed in the bone marrow which move through the circulation and migrate into the airways. The bone marrow transit time in humans is about 4.3 days. In peripheral blood the eosinophil has a half life of about 18 hours. Recruitment from the blood to the airway initially involves adherence of eosinophils to endothelial cells and subsequent migration into an inflammatory site. Inflammatory cytokines such as IL-1, IL-4, IL-5, interferon (IFN)-γ, and tumour necrosis factor (TNF)-α enhance the interaction between inflammatory cells and endothelial cells, and endothelial cells induce increased expression of adhesion molecules such as intercellular adhesion molecule 1 and vascular cell adhesion molecule, and transendothelial migration of eosinophils to inflamed tissues. In target lung tissue degradation of eosinophilic granules such as ECP, major basic protein, eosinophil derived neurotoxin, and eosinophil peroxidase is fundamental to the proinflammatory role of eosinophils. These eosinophilic granular contents damage the airway epithelium, stimulate the release of histamine from mast cells, directly contract airway smooth muscle, and promote airway hyperresponsiveness.

As previously suggested, in this study the eosinophil activation markers IL-5 and ECP significantly increased in patients with severe asthma. This suggests that the higher percentage of eosinophils and increased levels of eosinophil activation markers measured in asthmatic sputum are due to recruitment of eosinophils and degranulation of eosinophils in target tissues.

Apoptosis or programmed cell death is an ordered process of fundamental biological importance which is as vital to homeostasis as are cellular proliferation, differentiation, and migration. It is thought to be critically important in promoting the clearance of inflammatory cells and the resolution of inflammation. Apoptosis of eosinophils may be clinically relevant in asthma, promoting the removal of airway eosinophils and contributing to clinical improvement. IL-5, a cytokine that attracts, activates, and prolongs the survival of eosinophils, is very important in the pathogenesis of allergic inflammation and asthma. It has an inhibitory effect on eosinophil apoptosis by regulating bcl-2 expression. Dewson et al reported that cultivation of eosinophils in the presence of 100 pg/ml IL-5 for 24 hours significantly reduced apoptosis (p<0.01) to 10.7 (2.5)% compared with 46.8 (7.4)% in the absence of IL-5, suggesting that survival enhancing IL-5 modulates the expression of bcl-2 in vitro. We found that IL-5 was frequently detected in patients with severe to life threatening asthma and expression of bcl-2 significantly reduced apoptosis (p<0.01). We found that IL-5 was significantly increased in patients with severe asthma compared with those with mild asthma. The evaluation of bcl-2 expression in sputum eosinophils may be a useful marker for monitoring airway inflammation in asthma.

CORRELATIONS BETWEEN BCL-2+ EOSINOPHILS AND CLINICAL FINDINGS

There was a significant positive correlation between bcl-2+ eosinophils and ECP levels (r = 0.61, p<0.01). The proportions of sputum eosinophils were positively correlated with bcl-2+ eosinophils (r = 0.58, p<0.01). There was also a significant positive correlation between bcl-2+ eosinophils and IL-5 levels (r = 0.83, p<0.01, fig 3) and a significant negative correlation between bcl-2+ eosinophils and FEV1/FVC (r = -0.54, p<0.05, fig 4). No correlation was noted between bcl-2+ eosinophils in the sputum and atopy score or non-specific airway hyperresponsiveness.

Discussion

Inhibition of eosinophil apoptosis may play an important role in chronic airway inflammation. In this study we found that anti-apoptotic bcl-2 protein was increased in patients with severe...
protein in sputum eosinophils was related to the severity of asthma, suggesting that IL-5 prolongs the survival of eosinophils. Over-expression of bcl-2 has been shown to prolong cellular survival in myeloid leukemia cell lines and neutrophils, as well as lymphoid cell lines, by blocking apoptosis.

Assessment of apoptosis is performed using methods that evaluate the physical changes of the cell by light and electron microscopy, as well as detection of the classical fragmentation of intracellular DNA. Alternative approaches include detection of DNA degradation using flow cytometric methods and evaluation of the expression of apoptosis genes with techniques such as in situ hybridisation or Northern blotting. In this study we used immunocytochemical staining to detect apoptosis protein. Bcl-2+ eosinophils were significantly more numerous in the cytoplasm of sputum eosinophils from patients with severe to life threatening asthma than in those with mild to moderate asthma. Other studies such as in situ hybridisation, reverse transcriptase polymerase chain reaction (RT-PCR), and western blotting are needed to confirm bcl-2 expression in asthmatic sputum eosinophils.

There was a significantly positive correlation between bcl-2+ eosinophils and ECP levels and the proportions of sputum eosinophils were positively correlated with bcl-2+ eosinophils in the cytoplasm of sputum eosinophils from patients with severe to life threatening asthma than in those with mild to moderate asthma. Other studies such as in situ hybridisation, reverse transcriptase polymerase chain reaction (RT-PCR), and western blotting are needed to confirm bcl-2 expression in asthmatic sputum eosinophils.

In summary, we examined the expression of bcl-2 protein in the sputum of patients with asthma and found more bcl-2 protein in the sputum from patients with severe asthma than from patients with mild asthma. These results suggest a possible contribution of bcl-2 protein to asthmatic airway inflammation, including inhibition of eosinophil apoptosis.
