It is a matter of some concern to us that you felt obliged to print a notice of duplicate publication for Professor Corris. While we all deplore dual publication of original scientific data, the purpose of review articles is to provide a form of CME for practising physicians. It is therefore inevitable that, when an author in a field is asked to give their current view on a subject, there will be considerable overlap with his/her previous thoughts on the subject. This does not make the article uninteresting to read, nor—as we are sure the Editors are aware—does it stop such articles being frequently referenced. It is our belief that it is generally understood within the community that review articles by a given author are likely to contain significant overlap with previously published reviews by the same author and that, in this situation, it is rather “missing the point” to call this a duplicate publication.

To illustrate the point we enclose a list of review articles which all contain overlapping material concerning the assessment of respiratory muscle strength.** With the exception of the article in Thorax (for which the invitation to write came following a prompt from us), the remaining articles were all written as a result of unsolicited requests by the editorial team of the journal concerned. Like Professor Corris’s articles, they serve a useful function because these journals reach widely differing audiences and in each case the text of the article has been aligned to fit the interests of the readership of the journal concerned.

Our belief is that reviews of this sort do serve a useful role in postgraduate medical education and, because writing them is not recognised by the University Research Assessment Exercise, it is becoming increasingly hard to find experts in their fields who are prepared to do so. Publicly identifying this type of “duplicate publication” serves no useful purpose.

Editors’ reply

We published the statement on duplicate publication, as did the other journal concerned, in response to a complaint. As far as we are able to point out the similarity between the two articles. When we looked through the article published in Clinical Medicine it was evident that large parts of the article in Thorax were reproduced verbatim.

We appreciate that review articles by the same author in different journals often contain overlapping information, but that was not the point on this occasion. The point was that much of the material was exactly the same, and Professor Corris had not explicitly acknowledged this or the contribution of other authors to it.

We have taken a firm line on duplicate publication and non-disclosure of related publications in the past and, although we accept that some degree of duplicate reporting is acceptable and common in review or opinion articles, having received a formal complaint about the article we did not feel able to dismiss it. This was particularly the case since Professor Corris was until very recently an Associate Editor of Thorax, and we were in danger of being open to accusations of special privilege for people who have been associated with the journal.

Chlamydia pneumoniae and COPD exacerbation

We read with interest the recent paper by Blasi et al which showed that Chlamydia pneumoniae infection is associated with higher rates of exacerbation and airway microbial colonisation in patients with COPD. We have prospectively studied patients in the East London COPD study with daily monitoring using diary cards to detect COPD exacerbation defined using the same criteria. Serum microimmunofluorescence (MIF) immunoglobulin G (IgG) titres for C pneumoniae were measured in 110 patients (FEV1% 41.7 (18.4)) with stable COPD during 1 year with simultaneous estimation of plasma fibrinogen and serum interleukin 6 (IL-6); 26% of the patients had IgG titres of ≥1 in 16 (fig 1). High C pneumoniae IgG titres were not related to FEV1% predicted, exacerbation frequency, plasma fibrinogen, or serum IL-6 levels. In their paper Blasi et al did not report whether there was a relation between MIF titres and exacerbation frequency.

Blasi and colleagues found that 43% of patients when stable were positive for C pneumoniae by DNA polymerase chain reaction (PCR) using peripheral blood mononuclear cells (PBMCs). At exacerbation they have only shown data for the 34 (of 61) who consented to the antibiotic trial and all 34 were positive for C pneumoniae. In our study a further 33 patients (FEV1% 39.8 (16.3)) were simultaneously sampled using nasopharyngeal aspirate PCR adapted from Cunningham et al at stable baseline but nine patients (seven from induced sputum and another two in nasal aspirates)

IgG antibody inverse titres in 110 patients (28%) were positive for *C pneumoniae* microimmunofluorescence (MIF) IgG antibody inverse titres in 110 patients with stable COPD.

![Figure 1](Image)

**Figure 1** Distribution of serum *C pneumoniae* microimmunofluorescence (MIF) IgG antibody inverse titres in 110 patients with stable COPD.

(28%) were positive for *C pneumoniae* at exacerbation. The presence of *C pneumoniae* was not associated with smoking history, FEV1 %, peak flow change at or peak flow recovery from COPD exacerbation, rate of peak flow recovery, IL-6 (fig 2) or IL-8 levels, or total and differential cell counts in induced sputum. The lack of relationship between *C pneumoniae* detection and inflammatory markers at exacerbation suggests to us that *C pneumoniae* exacerbations are no different from exacerbations not associated with *C pneumoniae*.

We found no relationship between *C pneumoniae* detection in the airway at exacerbation and exacerbation frequency (p=0.504), but Blasi et al found that *C pneumoniae* positive patients (in stable COPD) had a greater tendency towards frequent exacerbation. However, the difference in exacerbation frequency between the two groups was small (0.6 exacerbations per year), and the authors need to be cautious about concluding that this difference could affect disease progression.

The main difference between the data of Blasi et al and ours is that in their study 16 of 42 patients (38%) enrolled in study 1 had *C pneumoniae* by DNA PCR and a similar number (61/141, 43%) in study 2 in PBMCs, both during stable COPD. We sampled only once in stable COPD and found none, despite finding 28% at exacerbation. Blasi and colleagues sampled subjects repeatedly (at least four times), but it is not clear how many times they had to be positive to be defined as “respiratory samples positive for *C pneumoniae*” by DNA PCR. The 16 positive patients provided 69 sputum samples; were all sputum samples positive on all occasions examined in these patients? Similarly, were all 125 sputum samples from the 26 patients who were *C pneumoniae* negative always negative?

It would be helpful if the authors could give the data on the chronic nature of infection in their sputum samples.

**Authors’ reply**

We are grateful to Seemungal et al for their comments regarding our recently published paper on *Chlamydia pneumoniae* and chronic bronchitis.1 Seemungal et al prospectively studied 110 patients with COPD for 1 year, evaluating serum microimmunofluorescence IgG titres, plasma fibrinogen, and IL-6 levels. They found no correlation between high IgG titres and FEV1 % predicted, exacerbation frequency, plasma fibrinogen, and serum IL-6 levels. We also found no correlation between serological results and FEV1 % predicted or exacerbation frequency. In fact, as in previous reports,2 we found a low degree of correlation between *C pneumoniae* serology and peripheral blood mononuclear cell (PBMC) PCR. A greater degree of correlation was observed when IgG and IgA titres were combined but, unfortunately, no comparison is possible as Seemungal et al only performed IgG titre determinations. In any case, our findings are not truly comparable with those of Seemungal et al as serology is known to be less specific than PCR for the identification of chronic infection with *C pneumoniae*.3

In the second part of their letter Seemungal et al report the results of an analysis on a further group of 33 patients who were simultaneously sampled for nasal aspirates and induced sputum when stable and during exacerbation. They found no PCR positivity in stable patients, whereas in nine of 43 exacerbations *C pneumoniae* was detected by PCR in respiratory specimens. The authors infer that DNA positivity in the sputum is a marker of *C pneumoniae* acute infection; this would mean that around 30% of all acute exacerbations are sustained by *C pneumoniae*. However, the gold standard for acute infection is still considered serology on paired samples. Applying both PCR and serology on paired serum samples we found an acute infection in two of 34 exacerbations confirming our previous data of an overall incidence of 5–6%.4 Their definition of acute *C pneumoniae* infection may explain, at least in part, why they could not detect any difference between exacerbations associated or not associated with *C pneumoniae* in terms of inflammatory response.

The reported discordance in PCR positivity on respiratory samples between our study and that of Seemungal et al may be related to different PCR techniques. In fact, we found 16/42 (38%) PCR positive patients with stable COPD, whereas they found 9/33 (28%) in stable COPD and during an exacerbation, respectively. Considering that the rate of positivity in our stable patients is comparable to that of patients with exacerbation in Seemungal et al’s series, we think that “our study indicate that PCR results may simply be related to PCR sensitivity, sputum quality/quantity, amount of DNA retrieved from the samples, and number of tested samples.” Seemungal et al tested a single induced sputum specimen for each stable patient whereas we analysed at least four spontaneous sputum samples for each stable patient. We defined any patient with at least two positive specimens as PCR positive. The authors’ definition of positivity in our stable patients is comparable with ours: PCR positive on the basis of 43/69 (62%) PCR positive sputum samples. Twenty six patients were considered PCR negative; 24 had repeatedly negative PCR results on all 113 sputum samples and two patients had a single PCR positive sputum specimen (2/12 specimens).

Our results on exacerbation frequency are based on the observation of 141 subjects for 2 years compared with 33 subjects in the study by Seemungal et al. The different number of subjects included in the two studies may explain some discrepancies. We do agree that caution is needed in interpreting the results of our study and stated that “we think that our study indicates the possible role of *C pneumoniae* chronic infection in disease progression in COPD patients. Further confirmation based on large scale trials is needed.” However, even a slight increase in exacerbation frequency may have a role in disease progression.5

Marginal benefits of adding formoterol

Price and colleagues' conclusion that adding formoterol confers a therapeutic advantage to inhaled steroids in patients with mild to moderate asthma. During the 6 month follow up in part II of the study the frequency of the secondary outcome of mild asthma exacerbations differed by 2.5 per patient per 6 months while the difference in poorly controlled asthma days was 2.2 days per patient per 6 months. These differences, while statistically significant, are unlikely to be of real clinical relevance. Indeed, during the same period the difference in quality of life was neither significant nor clinically relevant. The main differences which were significant in bronchial dilator sensitive outcomes such as peak flow and reliever use, which are to be expected when patients are taking a 24/7 bronchial dilator. These data are little different from those in steroid naive patients in the OPTIMA trial over 12 months where the addition of formoterol to low dose budesonide improved lung function but not exacerbations, while in the same trial the addition of formoterol conferred only a small but significant reduction in exacerbations in patients previously treated with corticosteroids.9

Pointedly, neither of these studies evaluated any inflammatory surrogates. We would therefore suggest that these trials indicate that most patients with mild to moderate asthma can be adequately controlled on low to moderate doses of inhaled budesonide alone, and that there is only a marginal advantage conferred by adding formoterol. Moreover, combination inhalers are considerably more expensive than inhaled steroid alone and their routine use is not warranted in primary care.

BOOK REVIEW

Respiratory Medicine Specialist Handbook

This is the first in a new series of specialist handbooks that aims to fill the niche between the comprehensive textbook and the pocket handbook. There are the obvious pitfalls of trying to squeeze in too much detail at the expense of accessibility or reducing the subject to little more than a series of disjointed notes. However, this book—for the most part—steers clear of both of these errors and has produced a very readable, yet reasonably detailed, summary of specialist respiratory medicine. The 31 chapters cover a wide variety of topics and the authors' list is like a "Who's Who?" of UK respiratory medicine.

It is possible to pick up this book, read a chapter in less than half an hour, and come away with an increased knowledge of the pathophysiology of the condition under study and, perhaps more usefully, the intricacies of practical management which is the focus of the book. It will therefore cater to the specialist registrar undergoing higher specialist training in providing a broad understanding in reasonable detail of most facets of respiratory medicine, but it could also be of use to the experienced physician in reaffirming, reminding, and refreshing of the basics, and perhaps updating knowledge with regard to more recent developments.

The book is attractively presented with short paragraphs of text interspersed with helpful tables and figures. For those who are stimulated to seek more information on any subject, each chapter has a selection of references for further reading. Whilst we all might aspire to read, study and inwardly digest a weighty, comprehensive tome of respiratory medicine, for most of us busy clinical practice this proves difficult. This reviewer would therefore encourage reading and studying this excellent book as an alternative which is more attainable and possibly of more practical relevance.
