**Development of a symptom specific health status measure for patients with chronic cough: Leicester Cough Questionnaire (LCQ)**

**Background:** Chronic cough is a common condition which has a significant impact on quality of life. Assessment and management are hampered by the absence of well validated outcome measures. The development and validation of the Leicester Cough Questionnaire (LCQ), a self-completed health related quality of life measure of chronic cough, is presented.

**Methods:** Patients with chronic cough were recruited from outpatient clinics. The development of the LCQ consisted of three phases: phase 1 (item generation); phase 2 (item reduction, allocation of items to domains and validation of questionnaire); phase 3 (repeatability and responsiveness testing of final version of questionnaire).

**Results:** Phase 1: Literature review, multidisciplinary team meeting and 15 structured interviews with chronic cough patients generated 44 items (LCQ1) with a 7 point Likert response scale. Phase 2: 104 chronic cough outpatients completed the LCQ1 along with an importance rating for each item. The clinical impact factor method was used for item reduction to 19 items (LCQ2: final version). These items were divided into three domains (physical, psychological and social) following expert opinion. Internal reliability, as assessed using Cronbach’s alpha coefficients, varied between 0.79 and 0.89. Concurrent validity was high when the LCQ2 (n=56) was compared with a cough visual analogue score (r=-0.72). There was a moderate relationship with response to the St George's Respiratory Questionnaire (r=-0.54) and SF36 total score (r=0.46). Phase 3: Two week repeatability (n=24) was high with intraclass correlation coefficients for domains varying between 0.88 and 0.96. Responsiveness in nine patients whose cough was successfully treated varied within domains from an effect size of 0.84 to 1.75.

**Conclusion:** The LCQ is a valid, repeatable 19 item self-completed quality of life measure of chronic cough which is responsive to change. It should be a useful tool in clinical trials and longitudinal studies.

**METHODS**

Patients with chronic cough were recruited from an adult respiratory outpatient clinic. Chronic cough was defined as a cough lasting more than 3 weeks that remained unexplained after assessment by the primary care physician. Patients were investigated and treated using a diagnostic protocol described previously. All patients with an isolated chronic cough were identified before the outpatient session, during which they were approached by another investigator who had not read the case notes. Patients were asked for their consent to participate in the development of the questionnaire and the protocol was approved by the Leicestershire ethics committee. The LCQ was developed using a multistep method divided into three phases: phase 1 (item generation); phase 2 (item reduction, allocation of items to domains, and validation of the questionnaire); and phase 3 (repeatability and responsiveness testing of final version of the questionnaire). The item reduction was based on questionnaire responses from 104 patients and concurrent validity was assessed in a separate 56 patients, 27 of whom had a cough sensitivity measurement.

**Phase 1: Item generation**

Phase 1 consisted of item generation for a preliminary questionnaire LCQ1 by the following processes: (1) critical review of health related quality of life (HRQOL) literature; (2) review of existing generic and respiratory specific HRQOL questionnaires; (3) multidisciplinary team meeting to generate items for the questionnaire which included respiratory and...
non-specialist doctors, nurse, asthma nurse specialist, physiotherapist, pharmacist and a rehabilitation expert involved in delivering care to patients with chronic cough. A layperson was also present at the meeting: (4) semi-structured interviews with 15 patients with chronic cough to outline areas of concern to them.

Phase 2: Item reduction, allocation of items to domains, and validation of the questionnaire

Item reduction

During phase 2, 104 patients with chronic cough were asked to answer each item of the LCQ1 and, in addition, to rate the importance of each item to them on a 5 point scale (1=not important, 5=extremely important). Data obtained from the LCQ1 were used to reduce items by the clinical impact factor method which selects items that are most frequently perceived as important by patients. The mean impact score for each item was calculated as the product of frequency of the item occurring (0–1.00) and mean importance rating of the item. Items were ranked based on their impact scores and an impact score threshold of 1.5 was used to eliminate low ranking items. The following criteria were used to further eliminate items from the questionnaire: (1) high ceiling effect (items with >60% of responses falling into the two lowest categories “none of the time” and “hardly any of the time”); (2) the lower impact score items of those with correlation coefficient >0.8; (3) items that were similar or ambiguously worded by consensus opinion. The remaining items formed the LCQ2, the final version (appendix 1).

Allocation of items to domains

Domains for the LCQ were predefined on: (1) World Health Definition of health, (2) semi-structured interviews held with patients for item selection process, and (3) expert opinion. Based on this, domains were physical, psychological, and social. Each item was allocated to one of the predefined domains using the following criteria: (1) each item’s face validity was determined by an expert panel, and (2) each item was correlated with each domain score to ensure that the item was in the most appropriate scale. Internal reliability of each domain was assessed using Cronbach’s alpha coefficients which indicate the extent to which the items are interrelated. Internal reliability is generally acceptable for domains with a Cronbach’s alpha coefficient of 0.7 or above.

Concurrent validity

Concurrent validity, which is the assessment of an instrument against other standards that provide an indication of the true value for the measurements, was assessed by correlating scores of LCQ2 with three health outcome measures completed at the same time in 56 patients: (1) cough visual analogue score (VAS) which has a scale from 0–100 mm with 100 mm being the worst imaginable cough, (2) St George’s Respiratory Questionnaire (SGRQ) which includes cough related items, and (3) Short Form 36 item (SF36) health status questionnaire which is a well tested and validated generic health status questionnaire which has a scale from 0–100 with 100 being the best health status. The time scale over which the symptoms or events were questioned in the SGRQ or SF36 was adjusted to 2 weeks to be consistent with the LCQ2. Twenty seven patients also had a cough reflex sensitivity test. The LCQ2 and cough VAS was administered in the outpatient clinic before and 2 months after a treatment had been commenced. Criteria for starting treatment and individual treatments used were as outlined previously. Patients were asked if their cough had improved.

Statistical analysis

SPSS version 10 was used for data analysis. Data are presented as mean (SE) or ranges. Both Pearson correlation coefficients and Spearman rank correlation coefficients were used to determine relationships within and between different outcome measures according to the distribution of the variables. Item to domain correlations were adjusted for over-fitting by removing the score from the item being considered from the total domain score. Agreement between domain and total scores for the first and second completion of the LCQ during repeatability testing were assessed using intra-class correlation coefficients. The 95% limit of agreement was calculated as 1.96 × standard deviation of within subject differences. Effect size for the total LCQ score was determined by the difference in mean total LCQ score before and after the intervention/SD of LCQ total scores before the intervention.

RESULTS

Phase 1: Item generation

A review of existing HRQOL questionnaires and literature and multidisciplinary team meeting generated an initial pool of 38 items. A further six items were added after patient interviews. A preliminary questionnaire (LCQ1) comprising 44 items was therefore obtained.

Phase 2: Item reduction, allocation of items to domains, and validation of questionnaire

One hundred and four patients completed the LCQ1. Patients had a mean (range) age of 57 (19–78) years, cough duration of 5 (0.2–50) years, cough VAS 48 (3–96) mm, and 39 (38%) were men.

Item reduction

Twenty five of the 44 items were omitted for the reasons given in table 1, which resulted in a questionnaire with 19 items.

Allocation of items to domains

Eight items were assigned to the physical domain, seven to the psychological domain, and four to the social domain by the expert panel. All items correlated well with their domains (Pearson correlations adjusted for over-fitting 0.4–0.8, all p<0.01). Internal consistency was high for all domains as well as the total score (table 2).

Concurrent validity

Fifty six patients completed the LCQ2 and other outcome measures. Patients had a mean (range) age of 55 (22–85) years, cough duration of 5 (0–7) years, cough VAS 48 (4–100) mm, and 21 (38%) were men. Correlations between
the 19 item LCQ2 and other outcome measures are presented in table 3. All were highly significant (p<0.001). Correlations did not change significantly when items common to both scales were excluded. Correlations between LCQ and SF36 domains were physical/role limitation due to physical problems (ρ=0.46), psychological/mental health (ρ=0.59), and social/social functioning (ρ=0.46). Pearson’s correlations between LCQ total score and cough sensitivity (logC2 and logC5) were 0.14 and 0.18, respectively (p=0.5 and 0.4, respectively, n=27). There were no significant correlations between cough sensitivity and LCQ domains or cough VAS.

**DISCUSSION**

The LCQ is a valid and reliable health status measure for adults with chronic cough. The final version contains 19 items with a 7-point Likert response scale. It is designed for self-administration and takes less than 5 minutes to complete. 68% of our patients found our questionnaire easier to complete and more relevant than two other widely used HRQOL measures. This may be because it is a patient derived questionnaire and hence has items, domains, and response scales that are more meaningful to them. The LCQ was highly repeatable and responsive to change, suggesting it might be a particularly useful outcome measure in assessing the response to treatment in the clinic and in trials.

Item reduction was performed using the clinical impact factor method instead of traditional psychometric techniques such as factor analysis. The impact factor chooses items which patients label as a problem and ranks the importance which they associate with them. Items are categorised into domains using clinical sensibility. The factor analysis approach is based largely on the structure of correlations between items, and investigators must also make a number of subjective decisions throughout the process. Factor analysis does not take into account the perception of clinical relevance of items by the intended population. Instead, item reduction is performed predominantly on complex correlations between items. Many items chosen during questionnaire development will be significant using both techniques, but there are important
differences. We share the views of Juniper et al. that all items of functional impairment that are important to patients should be included in a disease specific quality of life health status measure, irrespective of their association with each other.

One limitation of the study was our limited ability to explore the relationship between the LCQ and other objective markers of cough severity. This is due to the lack of well validated outcome measures in chronic cough. However, the LCQ correlated well with the cough VAS and less well with cough sensitivity suggesting that, as in asthma, the relationship between symptoms, quality of life, and physiological impairment is complex. An absence of correlation between cough symptoms and cough sensitivity has also been noted in patients with cryptogenic fibrosing alveolitis and chronic obstructive pulmonary disease. As expected, the LCQ correlated moderately with the SGRQ which has four specific cough items out of many respiratory items and less so with SF36 which focuses on general health alone, providing evidence of concurrent validity.

The LCQ was shown to be highly repeatable over 2 weeks. This was better than the repeatability of other measures of chronic cough such as cough VAS and cough sensitivity. Our data indicate that a change in total LCQ score of more than 2.56 is likely to be significant since this lies outside the 95% limit of agreement. We have also shown that the LCQ was responsive to change after treatment although the effect sizes were less than that seen with the cough VAS, suggesting that the latter might be the outcome measure of choice in clinical trials. Effect sizes were comparable to that seen with cough sensitivity measurement in a study where inhaled corticosteroids were given for cough due to eosinophilic bronchitis (effect sizes for C2 and C5: 1.72 and 1.17, respectively). These characteristics suggest that the LCQ can detect changes in health status as a result of successful treatment.

Since this paper was submitted, French et al. have described the validation of another cough specific quality of life questionnaire (CQLQ). The LCQ is a briefer questionnaire with fewer domains than the CQLQ which comprises 28 items and six domains. The latter questionnaire also differs from ours in that it used factor analysis for allocation of items to domains, subjective criteria for item reduction, and provided more limited information on concurrent validity against other measures. Further work is necessary to compare the LCQ and CQLQ in the assessment of chronic cough in European and North American populations.

This study suggests that the LCQ will be suitable for a number of applications. Firstly, it would be useful in describing longitudinal changes that take place in patients with chronic cough. It can be used to identify aspects of health affected by cough and how these change over time. Finally, it can be used in clinical trials evaluating new treatments for cough and their effect on health related quality of life. In summary, the LCQ is a brief, easy to administer, and well validated chronic cough HRQOL questionnaire. It represents an advance in the management of chronic cough where there is a lack of objective measures to guide the clinician and scientist.

APPENDIX 2: Scoring of LCQ

1. Domains (questions):
   (a) Physical: 1, 2, 3, 9, 10, 11, 14, 15
   (b) Psychological: 4, 5, 6, 12, 13, 16, 17
   (c) Social: 7, 8, 18, 19

2. Domain scores: total score from domain/items

3. Total scores: addition of domain scores (range 3–21).

ACKNOWLEDGEMENTS

The authors would like to thank Paula Billington, Wendy Chawner and the out patient clinic staff for their help in administering the questionnaire.

**APPENDIX 1: Leicester Cough Questionnaire. © 2001**

This questionnaire is designed to assess the impact of cough on various aspects of your life. Read each question carefully and answer by CIRCLING the response that best applies to you. Please answer ALL questions, as honestly as you can.

1. In the last 2 weeks, have you had chest or stomach pains as a result of your cough?
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

2. In the last 2 weeks, have you been bothered by sputum (phlegm) production when you coughed?
   - 1: Every time
   - 2: Most times
   - 3: Several times
   - 4: Some times
   - 5: Occasionally
   - 6: Rarely
   - 7: Never

3. In the last 2 weeks, have you been tired because of your cough?
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

4. In the last 2 weeks, have you felt in control of your cough?
   - 1: None of the time
   - 2: Hardly any of the time
   - 3: A little of the time
   - 4: Some of the time
   - 5: A good bit of the time
   - 6: Most of the time
   - 7: All of the time

5. How often during the last 2 weeks have you felt embarrassed by your coughing?
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

6. In the last 2 weeks, my cough has made me feel anxious
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

7. In the last 2 weeks, my cough has interfered with my job, or other daily tasks
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

8. In the last 2 weeks, I felt that my cough interfered with the overall enjoyment of my life
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

9. In the last 2 weeks, exposure to paints or fumes has made me cough
   - 1: All of the time
   - 2: Most of the time
   - 3: A good bit of the time
   - 4: Some of the time
   - 5: A little of the time
   - 6: Hardly any of the time
   - 7: None of the time

10. In the last 2 weeks, has your cough disturbed your sleep?
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

11. In the last 2 weeks, how many times a day have you had coughing bouts?
    - 1: All of the time (continuously)
    - 2: Most times during the day
    - 3: Several times during the day
    - 4: Some times during the day
    - 5: Occasionally through the day
    - 6: Rarely
    - 7: None

12. In the last 2 weeks, my cough has made me feel frustrated
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

13. In the last 2 weeks, my cough has made me feel fed up
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

14. In the last 2 weeks, have you suffered from a hoarse voice as a result of your cough?
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

15. In the last 2 weeks, have you had a lot of energy?
    - 1: None of the time
    - 2: Hardly any of the time
    - 3: A little of the time
    - 4: Some of the time
    - 5: A good bit of the time
    - 6: Most of the time
    - 7: All of the time

16. In the last 2 weeks, have you worried that your cough may indicate serious illness?
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

17. In the last 2 weeks, have you been concerned that other people think something is wrong with you, because of your cough?
    - 1: All of the time
    - 2: Most of the time
    - 3: A good bit of the time
    - 4: Some of the time
    - 5: A little of the time
    - 6: Hardly any of the time
    - 7: None of the time

18. In the last 2 weeks, my cough has interrupted conversation or telephone calls
    - 1: Every time
    - 2: Most times
    - 3: A good bit of the time
    - 4: Some times
    - 5: Occasionally
    - 6: Rarely
    - 7: Never

19. In the last 2 weeks, I feel that my cough has annoyed my partner, family or friends
    - 1: Every time I cough
    - 2: Most times
    - 3: Several times when I cough
    - 4: Some times when I cough
    - 5: Occasionally when I cough
    - 6: Rarely
    - 7: Never

Thank you for completing this questionnaire.
