**INTERSTITIAL LUNG DISEASE**

Losartan attenuates bleomycin induced lung fibrosis by increasing prostaglandin E2 synthesis

Background: The angiotensin system has a role in the pathogenesis of pulmonary fibrosis. This study examines the antifibrotic effect of losartan, an angiotensin II type 1 receptor antagonist, in bleomycin induced lung fibrosis and its possible implication in the regulation of prostanoid E2 (PGE2) synthesis and cyclooxygenase-2 (COX-2) expression.

**Methods:** Rats were given a single intratracheal instillation of bleomycin (2.5 U/kg). Losartan (50 mg/kg/day) was administrated orally starting one day before induction of lung fibrosis and continuing to the conclusion of each experiment.

**Results:** Losartan reduced the inflammation induced by bleomycin, as indicated by lower myeloperoxidase activity and protein content in the bronchoalveolar lavage fluid. Collagen deposition induced by bleomycin was inhibited by losartan, as shown by a reduction in the hydroxyproline content and the amelioration of morphological changes. PGE2 levels were lower in fibrotic lungs than in normal lungs. Losartan significantly increased PGE2 levels at both 3 and 15 days. A reduction in COX-2 expression by bleomycin was seen at 3 days which was relieved by losartan.

**Conclusions:** The antifibrotic effect of losartan appears to be mediated by its ability to stimulate the production of PGE2. Losartan, which is already widely used clinically, could be assessed as a new treatment in lung fibrosis.
Chemicals
Bleomycin sulphate was obtained from Almirall-Prodésfarma (Barcelona, Spain), halothane (Fluothane) from Zeneica Farma (Pontevedra, Spain), and sodium pentobarbital from Normon (Madrid, Spain). Losartan was provided by Merck and Co (West Point, PA, USA).

Experimental model
Animals were anaesthetised under halothane and a single dose of 2.5 U/kg bleomycin dissolved in sterile saline (0.9% NaCl) was instilled intratracheally via the transoral route by a small glass device developed especially for it. Control animals received the same volume of intratracheal saline solution. The dose of bleomycin was selected from previous experiments to cause no mortality but consistent biochemical and histological damage. The duration of each experiment was 3 or 15 days post-instillation. The animals were sacrificed at the end of each experiment by a lethal injection of sodium pentobarbital (100 mg/kg ip) followed by exsanguination from the abdominal aorta. Lung tissues were weighed and processed separately for bronchoalveolar lavage, biochemical, and histological studies as described below.

Experimental groups
Animals were randomly distributed into four groups in each experiment: (1) sterile saline solution (vehicle for bleomycin) + water (vehicle for losartan) (n = 4); (2) sterile saline solution + losartan (n = 4); (3) bleomycin + water (n = 8); (4) bleomycin + losartan (n = 8).

Losartan (50 mg/kg/day) or water was administered orally (at 09.00 hours) starting one day before the instillation of bleomycin and continuing up to the end of the experiment. The treatment was dissolved in a final volume of 1–2 ml distilled water. The experimental groups were repeated twice at 3 days and at 15 days. Oral administration was selected as this is usual in the clinical setting, and the dose level and schedule were based on previous studies.

Biochemical studies
Neutrophil infiltration was assessed by measuring myeloperoxidase (MPO) activity. MPO was measured photometrically with 3,3',5,5'-tetramethylbenzidine as a substrate. Lung samples were macerated with 0.5% hexadecyltrimethylammonium bromide in 50 mM phosphate buffer at pH 6.0. Lung homogenates were disrupted for 30 seconds using a Labsonic sonicator (B Braun) at 20% power and subjected to three cycles of snap freezing in dry ice and thawing before a final 30 second sonication. Samples were incubated at 60°C for 2 hours and then spun down at 4000g for 12 minutes. The supernatants were collected for MPO assay. Enzyme activity was assessed photometrically at 630 nm. The assay mixture consisted of 20 μl supernatant, 10 μl tetramethylbenzidine (final concentration 1.6 mM) dissolved in DMSO, and 70 μl H₂O₂ (final concentration 3.0 mM) diluted in 80 mM phosphate buffer, pH 5.4. The results are expressed as units (U) MPO activity per lung.

Lung hydroxyproline (HP) content was measured as an indicator of collagen deposition by the method outlined by Woesnner. Lung samples were homogenised and then hydrolysed in 6 N HCl for 18 hours at 110°C. The hydrolysate was neutralised with 2.5 M NaOH. Aliquots (2 ml) were analysed for HP content after the addition of chloramine T (1 ml), perchloric acid (1 ml), and dimethylaminobenzaldehyde (1 ml). Samples were read for absorbance at 550 nm in a spectrophotometer. The results are expressed as μg HP per lung.

Bronchoalveolar lavage fluid
BAL fluid was obtained by cannulating the trachea and lavaging four times with 10 ml NaCl 0.9%. The BAL fluid was centrifuged (300g, 10 minutes, 4°C) and the supernatant was used for biochemical studies. Total protein concentration was measured by a standard dye technique (BioRad; Munich, Germany). The levels of PGE₂ were measured by a competitive enzyme immunoassay kit (Cayman Chemical; Ann Arbor, MI, USA) following the manufacturer’s protocol.

RNA preparation and RT-PCR of COX-2
Total RNA was prepared with Trizol reagent following the manufacturer’s instructions (GibcoBRL, Life Technologies) and RNA concentrations were calculated from A₂₆₀ determinations. RNA integrity and loading amounts were assessed by examining 18S and 28S ribosomal RNA banding of samples electrophoresed in 1% agarose gel under non-denaturing conditions and stained with ethidium bromide. Analysis of COX-2 and β-actin mRNA expression was done using a semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) method. One μg total RNA was used and the sequences amplified by the Life Technologies One Step RT-PCR System according to the manufacturer’s protocol. The forward primer for COX-2 was 5’-GCT-GTA-CAA-GCA-GTG-GCA-AA-3’ and the reverse primer was 5’-ATG-CTG-GCT-GTC-CTG-TTG-GA-G-3’. For β-actin the forward primer was 5’-TCA-AGT-AGT-AGG-TAT-ACA-TCC-GT-3’ and the reverse primer was 5’-CCT-AGA-AGC-ATT-TGC-GGT-GCA-CGA-TG-3’. Sequences were resolved by electrophoresis in denaturing 1.8% agarose gel and staining with ethidium bromide.

Lung histological studies
Histological evaluation was carried out on lungs that were not lavaged. The lungs were first perfused through their main bronchus with a fixative solution (10% neutral buffered formaldehyde) and then washed with saline solution. The lungs were then dried, embedded in paraffin, sectioned, and stained with haematoxylin and eosin. The sections were examined by light microscopy and photographed. The degree of inflammation and the extent of fibrosis were assessed by a blinded histopathologist. The histological scores were calculated as the percentage of lung area occupied by inflammatory cells or fibrotic tissue.

Figure 1 Relationship between lung weight and body weight at (A) 3 days and (B) 15 days. There was a significant increase in the lung/body weight relationship after bleomycin (BLM) administration at 3 days (*p = 0.001 versus control group) and at 15 days (*p = 0.001 versus control group). Losartan (LOS) had no effect on this relationship (3 days: p = 0.84, 15 days: p = 0.88). Statistical analysis was performed by one way ANOVA followed by Student’s t test.
formalin) at a pressure of 25 cm H₂O, immersed in the fixative for 12–24 hours, and blocks were taken. Tissue paraffin blocks were cut into 4 μm thick sections and stained with haematoxylin-eosin and Masson’s trichrome to identify inflammatory cells, connective tissue, and collagen deposition. The histological changes were evaluated by a descriptive method.

**Statistical analysis**

Data are expressed as mean (SE) with 95% confidence intervals (CI) of n experiments. Statistical analysis was carried out by analysis of variance (ANOVA) followed, when differences were significant, by appropriate post hoc tests including the Newman-Keuls tests. Differences between groups were tested using the paired Student’s t test (GraphPad Software Inc, San Diego, CA, USA). Differences were considered statistically significant when p was <0.05.

**RESULTS**

**Effect of losartan on bleomycin induced lung inflammation and collagen deposition**

The mean (SE) lung/body weight ratio was significantly increased in fibrotic rats induced by bleomycin both at 3 days (control group: 0.0045 (SE 0.0001) (95% CI 0.0046 to 0.0047); bleomycin group: 0.0077 (SE 0.0003) (95% CI 0.0071 to 0.0083)) and at 15 days (control group: 0.0040 (SE 0.0002) (95% CI 0.0037 to 0.0043); bleomycin group: 0.0084 (SE 0.0012) (95% CI 0.0071 to 0.0098)). Losartan treatment did not have a significant effect on this ratio (fig 1A and B).

An increase in MPO activity was observed in bleomycin exposed rats compared with the control groups at 3 and 15 days after bleomycin instillation (3 days: control group 146.8 (5.2) U/lung (95% CI 138.4 to 155.1), bleomycin group 399 (28.7) U/lung (95% CI 350.3 to 447.7); 15 days: control group 279.5 (103.9) U/lung (95% CI 177.6 to 381.4), bleomycin group 1000 (16.4) U/lung (95% CI 968 to 1032)). This increase was significantly reduced by losartan (3 days: bleomycin + losartan group 247.1 (28.6) U/lung (95% CI 198.5 to 295.7), 15 days: bleomycin + losartan group 869.4 (24.9) U/lung (95% CI 832.1 to 906.7)).

**Figure 2** Effect of losartan (LOS) on lung inflammation induced by bleomycin (BLM) assessed by myeloperoxidase (MPO) activity (U/lung) in lung tissue at (A) 3 days and (B) 15 days. Bleomycin induced a rise in MPO activity at both 3 and 15 days (p<0.001 versus control group at 3 days; p<0.001 versus control group at 15 days). At 3 days losartan reduced the total protein production initially induced by BLM (p=0.04 versus BLM group). No differences were found between the BLM group and BLM + LOS group at 15 days (p=0.11, fig 3B). Statistical analysis was performed by one way ANOVA followed by Student’s t test.

**Figure 3** Effect of losartan (LOS) on lung inflammation induced by bleomycin (BLM) measured by protein content in BAL fluid (mg/100 g) at (A) 3 days and (B) 15 days. Protein in BAL fluid increased after BLM instillation on days 3 and 15 (p<0.001 versus control group at 3 days; p=0.04 versus control group at 15 days). At 3 days losartan reduced the total protein production initially induced by BLM (p=0.04 versus BLM group). No differences were found between the BLM group and BLM + LOS group at 15 days (p=0.11, fig 3B). Statistical analysis was performed by one way ANOVA followed by Student’s t test.

**Figure 4** Antifibrotic effect of losartan (LOS) on bleomycin (BLM) induced lung fibrosis quantitatively measured using hydroxyproline (HP) content (μg/lung) at 15 days. The increased amount of HP content after BLM induction was inhibited by LOS. Statistical analysis was performed using one way ANOVA followed by Student’s t test: *p<0.001 versus control group; †p<0.001 versus BLM group.
Losartan in pulmonary fibrosis

No differences in PGE2 synthesis (p = 0.9), but LOS treatment upregulated BLM group. At 15 days rats instilled with saline solution or BLM showed increased the level of PGE2 (control group: 33849.1 (2065.6) pg/lung (95% CI 28309.6 to 41843.1), fig 5A). There were no significant differences in the amount of PGE2 between control and BLM groups 15 days after fibrotic induction. Losartan treatment significantly increased the PGE2 concentration at 15 days (control group: 63520.3 (9189.5) pg/lung (95% CI 47922.1 to 79118.4); bleomycin group: 64999.6 (2807) pg/lung (95% CI 59735 to 69264.1); bleomycin + losartan group: 81419.1 (5542.5) pg/lung (95% CI 71361.8 to 91476.4), fig 5B).

The expression of COX-2 mRNA was generally lower 3 days after bleomycin instillation. Fibrotic rats treated with losartan expressed a significantly increased amount of COX-2 mRNA at 3 days (control group: 0.38 (0.003) (95% CI 0.37 to 0.38); bleomycin + losartan group: 0.59 (0.03) (95% CI 0.54 to 0.64), fig 6A). There were no changes in COX-2 mRNA expression at 15 days after bleomycin instillation and no significant differences were observed in the losartan group (control group: 0.59 (0.03) (95% CI 0.54 to 0.64), fig 6B).

**Histological features**

Haematoxylin-eosin and Masson’s trichrome stained lung sections were examined by light microscopy. Lungs from control groups at 3 and 15 days were histologically normal (data not shown). The administration of bleomycin resulted in characteristic histological changes including areas of inflammatory infiltration, thickening of alveolar walls (fig 7A) and an increase in interstitial collagen deposition and fibroblastic appearance (fig 7B). Losartan treatment significantly reduced the changes in lung morphology; there were fewer inflammatory infiltrates (fig 7C), less collagen deposition, and septal widening (fig 7D).
We have shown that losartan, a selective AT1 receptor antagonist, ameliorates experimental lung fibrosis induced by bleomycin and increases PGE2 synthesis. Our findings provide further evidence for the antifibrotic effect of losartan and support the potential role of PGE2 as a protective molecule in lung fibrosis.

ANGII has been shown to be an important mediator in the pathogenesis of lung fibrosis and may influence the progression of lung injury via a number of mechanisms.25 It has been reported that there is an increase in lung ANGII concentration, which precedes increases in lung collagen, and an upregulation in AT1 receptor expression in lung parenchyma after bleomycin induced lung injury.11 12 25 The presence of a pulmonary renin-angiotensin system within the lung has been suggested several times in the literature. It has been reported that angiotensinogen and AT1 receptors are expressed in lung tissue.26 Moreover, a high concentration of ACE in BAL fluid has been observed in patients with sarcoidosis and IPF.27

The study shows that losartan significantly decreased lung inflammatory infiltration both early (3 days) and late (15 days) after bleomycin exposure. The anti-inflammatory effect of AT1 receptor blockade has been reported in previous studies.25 28 29 Our findings agree with those of Otsuka et al25 who showed that candesartan cilexetil significantly decreases the concentration of neutrophils in BAL fluid in the bleomycin model of pulmonary fibrosis, suggesting that ANGII may play a role in neutrophilic infiltration in the lung. Our study also confirms that losartan is effective in reducing lung fibrosis induced by bleomycin. Controversially, a recent study by Keogh et al30 has reported that losartan cannot attenuate the collagen deposition induced by bleomycin in mice. Differences in the animal model, the dose of bleomycin and losartan, and the time point of HP measurements may account for discrepancies between our results and those of Keogh et al.30 Nevertheless, a large number of previous reports have shown that AT1 receptor antagonists decrease lung collagen deposition, in accordance with our observations.11 25 31

The mechanisms of the pulmonary antifibrotic effect of AT1 receptor antagonists have been investigated in recent years.11–13 25 It is known that losartan inhibits the proliferation of human lung fibrotic fibroblasts induced by ANGII in vitro, through the activation of AT1 receptor and mediated by TGF-β.24 Renzoni et al have reported that the ANGII receptor type 1 gene is one of the most relevant targets of TGF-β in primary lung fibroblasts from patients with IPF.25 In the bleomycin model of pulmonary fibrosis, administration of losartan or candesartan cilexetil attenuates TGF-β expression and lung collagen deposition.11 25 Similarly, other observations suggest that the antifibrotic effect of losartan could involve the regulation of TGF-β expression, providing further insights into the links between profibrotic mediators in the pathogenesis of pulmonary fibrosis. The present study was designed to investigate whether losartan can also act through antifibrotic mediators.

The most relevant finding in our study was the effect of losartan on PGE2 synthesis and COX-2 expression. Losartan
significantly reversed the decrease in PGE₂ synthesis induced by bleomycin. A growing body of evidence supports the hypothesis that PGE₂ has a crucial role in the modulation of tissue repair and lung fibrosis.³³ PGE₂ inhibits fibroblast migration and proliferation in response to various mitogens and abrogates TGF-β-induced collagen production.³⁶ In addition, fibrotic fibroblasts exhibit a marked reduction in the ability to upregulate PGE₂ synthesis in response to TGF-β, with the consequent loss of the antiproliferative response to TGF-β mediated by PGE₂.³⁸ Moreover, lung epithelial cells are a major source of PGE₂, and the capacity of these cells to inhibit fibroblast proliferation is related to their ability to produce PGE₂.³⁹ It appears that these changes are important in transforming the fibroblast from a relatively passive cell into a crucial component of IFP pathogenesis.³¹ We hypothesised that the increased amount of ANGII may suppress the induction of PGE₂ synthesis, and this may result in an imbalance between profibrotic and antifibrotic mediators. Thus, reduction in the activity of ANGII would enhance the protective effect of PGE₂ in the fibrotic process. Our results confirm that AT1 antagonism increases PGE₂ and reduces collagen deposition. Taken together, these observations indicate that losartan acts on at least two of the most crucial mediators implicated in lung fibrosis, improving the balance between profibrotic (TGF-β₁) and antifibrotic (PGE₂) mediators.

The analysis of COX-2 mRNA expression showed that losartan reversed the reduction of COX-2 induced by bleomycin at 3 days, but no significant differences were found at 15 days. These results concur with studies in the kidney in which it was shown that ANGII inhibits COX-2 expression in rat renal cortex and that the administration of either captopril or losartan increases this expression.³⁷ However, the mechanisms involved in the regulation of COX-2 by ANGII in pulmonary fibrosis have not been investigated. The relevance of COX-2 as a protective mediator of pulmonary fibrosis has been demonstrated in vivo and in vitro,¹⁷ in vivo COX-2 is the major source of the PGE₂ synthesised by alveolar epithelial cells.³⁷ The failure to synthesise PGE₂ in fibroblasts and lung tissue from patients with IPF has been shown to be associated with a decreased capacity to upregulate COX-2.³⁸–³¹ Interestingly, the increased PGE₂ level observed in lung fibroblasts under losartan treatment did not correlate with a significant increase in COX-2 mRNA expression. This could be a consequence of the fact that AT1 antagonists also have an effect on other enzymes implicated in PGE₂ synthesis such as PGE₂ synthase, a hypothesis which requires future investigation.

In summary, our study shows that losartan enhances PGE₂ synthesis in experimental lung fibrosis and provides new insights into how AT1 receptor antagonists act against lung fibrosis. In addition, these data throw new light on the importance of ANGII as a regulator of the other main mediators implicated in the fibrotic process. This is a new approach to the molecular mechanisms implicated in the lung fibrotic process which could provide new insights for future treatments in lung fibrosis.

Infants too young to receive pneumococcal conjugate vaccine benefit from herd immunity

The Netherlands and the UK have recently joined a relatively small number of European countries to recommend a heptavalent pneumococcal conjugate vaccine (PCV7) as part of universal childhood immunisation programmes. PCV7 was incorporated into the US childhood vaccination programme in June 2000 and is recommended for all children aged 2–23 months. Since is introduction, evidence has shown that the rate of invasive pneumococcal disease (IPD) among children younger than 2 years has reduced by at least 60%. This study investigated for the first time rates of IPD in children aged 0–90 days before and after the introduction of PCV7.

A prospective population based study was undertaken with active laboratory based surveillance for IPD in infants aged 0–90 days across eight US states before (July 1997–June 2000) and after (July 2001–June 2004) the introduction of PCV7. The mean rates of IPD for infants aged 0–90 days decreased 40% from 11.8 (95% CI 9.6 to 14.5) to 7.2 (95% CI 5.6 to 9.4; p = 0.004) per 100 000 live births following PCV7 introduction. Notably, there was a significant decrease of 42% from 7.3 (95% CI 5.6 to 9.5) to 4.2 (95% CI 3.0 to 5.9; p = 0.01) per 100 000 live births in rates of IPD among infants aged 0–60 days—that is, those too young to receive the vaccine. Furthermore, subgroup analysis by race showed that the previous disproportionately high incidence of IPD in black compared with white infants was eliminated after the introduction of PCV7.

The authors conclude that this is the first study to suggest that neonates and infants too young to receive PCV7 are benefiting from herd immunity. They emphasise the importance of continued surveillance of IPD to observe if the trend continues, and to determine if serotypes not included in PCV7 emerge as an important cause of IPD in neonates and young infants.
