Intracardiac extension of lung cancer via the pulmonary vein

A 69-year-old male heavy smoker had intermittent haemoptysis for 1 month. He did not have exertional dyspnoea, palpitations or chest pain. Chest radiography showed a mass over the right lower lung (RLL). A CT scan of the chest revealed a dumbbell-shaped tumour with an irregular mass in the RLL field, with a tubular part extending along the right inferior pulmonary vein (fig 1A, arrowheads) and an oval tumour in the left atrium (fig 1A, asterisk). Transthoracic echocardiography through the apical four-chamber view showed an intracardiac tumour (asterisk, fig 1B) protruding from the right pulmonary vein (arrowheads, fig 1B). A complete staging investigation, including bronchoscopy, head CT scan and whole body bone scintigraphy, did not show any distant metastasis.

Despite failure to obtain tissue via transthoracic needle biopsy, RLL lobectomy and excision of the left intra-atrial tumour were performed based on the potential life-threatening situation. The surgical specimen (fig 2A) showed the same features as those seen on the chest CT scan. Pathological examination showed small cell lung cancer with cancerous thrombus formation in the pulmonary vein (fig 2B) and left atrium without wall invasion. The patient underwent surgery uneventfully and received adjuvant chemotherapy thereafter.

Lung cancer is one of the most common causes of metastatic cardiac tumours, but very few cases of intracardiac extension via the pulmonary vein are seen. If left untreated, patients may die from sudden cardiac arrest due to cardiac inflow obstruction or massive tumour emboli involving the major organs.1, 2

Learning points

- Small cell lung cancer, though rare, can develop intravascular cancerous thrombus along the pulmonary vein with intracardiac extension.
- Timely surgical intervention can be life-saving to prevent patients from sudden cardiac arrest due to intracardiac extension of lung cancer.
