Results The prognostic scoring model was: \( (25.5 + \text{age in years}/10) + 2 \) (if a repeat episode of PCP) + 4 (if PKS detected) + 4 (if Comorb present) – \( \text{PaO}_2 \) – \( \text{Hb} \). The prognostic model produced scores ranging from 0 to 20; median (IQR) = 9 (7–11). Testing interactions between risk factors and time showed the model to be applicable across all time periods. Patients were divided into five groups according to prognostic score: 0–3 = group 1, 4–7.9 = group 2, 8–11.9 = group 3, 12–15.9 = group 4, 16 or greater = group 5. Abstract S129 Table 1 shows mortality rates among the 540 patients with FCT, grouped according to their prognostic scores.

Conclusions While this prognostic scoring model requires further validation in patient cohorts from other healthcare institutions, it is potentially a simple ‘by the bedside’ method of identifying patients early in their hospital admission who are at high and low risk of in-hospital death from PCP and so may aid the clinician in assessing the severity of illness and in deciding on treatment strategies.

S130 OUTCOMES OF PSEUDOMONAS ERADICATION THERAPY IN PATIENTS WITH NON-CYSTIC FIBROSIS BRONCHIECTASIS
doi:10.1136/thx.2010.150946.31
L White, G Mirani, M Grover, J Rollason, A Malin, J Suntharalingam. Royal United Hospital, Bath, UK

Introduction and objectives In patients with non-cystic fibrosis (CF) bronchiectasis, Pseudomonas aeruginosa infection is associated with increased hospital admissions, poorer quality of life and accelerated lung function decline. The BTS guidelines recommend early Pseudomonas eradication therapy. However, despite clear evidence in CF, there is little evidence in non-CF bronchiectasis. Since 2004, we have initiated eradication therapy following initial Pseudomonas infection in non-CF bronchiectasis patients. This retrospective study assessed clinical and microbiological outcomes.

Methods All patients undergoing Pseudomonas eradication therapy from 2004 to 2010 were identified from our electronic database. Therapy included intravenous, oral and nebulised antibiotics. Patients were assessed for microbiological eradication, exacerbation frequency (measured by number of antibiotic courses), hospital admissions, clinical symptoms and lung function.

Results 30 patients were identified. 21 (67.7%) were females and mean age was 62.2 years. Median follow-up time was 26.4 months. Eradication therapy involved 2 weeks of intravenous antibiotics (12 patients), intravenous antibiotics followed by oral ciprofloxacin (13 patients) or oral ciprofloxacin alone (five patients), combined with 1–4 months of nebulised colomycin in 26 patients. Pseudomonas was initially eradicated from sputum in 24 patients (80.0%). 13 patients (43.3%) remained Pseudomonas-free at latest follow-up. 11 patients (36.7%) were subsequently reinfected with median time to reinfection of 6.2 months (Abstract S130 Figure 1). 17 patients with chronic infection were maintained on regular nebulised antibiotics. Exacerbation frequency was significantly reduced, with mean number of antibiotic courses per year 3.93 pre-eradication, and 2.09 post-
eradication (p=0.002). Mean number of hospital admissions per year were similar, at 0.39 pre-eradication and 0.29 post-eradication (p=NS). At first follow-up, 20 patients (66.7%) reported overall clinical improvement, with reduced cough in 12 (40.0%), reduced sputum volume in 14 (46.7%) and reduced sputum purulence in 11 (36.7%). Of the 21 patients followed up at 6 months, 26% (8/31) had further overall improvement and 13 (61.9 %) remained stable. Lung function was not affected by eradication therapy, with mean percentage predicted FEV1 62.1% pre and 64.1% post-eradication (p=NS).

Conclusion This study demonstrated that Pseudomonas eradication therapy can lead to prolonged clearance of this organism and highly significantly reduces exacerbation rate. This important outcome requires confirmation in a prospective study.

FATIGUE IN BRONCHIECTASIS: ITS RELATIONSHIP TO PSEUDOMONAS COLONISATION, DYSPNOEA AND AIRFLOW OBSTRUCTION

doi:10.1136/thx.2010.150946.32

1J G Macfarlane, 1H Tedd, 2P McAlinden, 2*Small, 3L Rostron, 3J Newton, 4A De Soyza. 1Freeman Hospital Respiratory Department, Newcastle upon Tyne, UK; 2William Leech Clinical Research Centre, Newcastle upon Tyne, UK; 3Institute of Ageing and Health, Newcastle University, Newcastle upon Tyne, UK; 4Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK

Introduction and objectives Fatigue is a complex and disabling symptom in non-CF bronchiectasis (nCF-Br) and can be formally measured using the Fatigue Impact Scale (FIS). FIS scores of >40 out of 120 are clinically significant. The FIS score has been shown to be prognostic of premature death in Primary Biliary cirrhosis but is not linked to markers of organ dysfunction (liver function tests). As poorer outcomes have been recently reported in Pseudomonas infected nCF-Br patients we aimed to measure the correlation between FIS scores and parameters of severity in nCF-Br.

Methods FEV1% predicted, MMRC dyspnoea score (MMRCD) and airflow obstruction (PSEUDOMONAS) were recorded in stable adult nCF-Br patients attending specialist clinic. All previous sputum cultures isolating Pseudomonas aeruginosa were reviewed. Two groups of patients were studied: those with Pseudomonas ‘colonisation’ (organism cultured ≥2 occasions, ≥3 months apart within 1-year period) and those with ‘isolation’ (organism cultured ≥1 occasion). Statistical comparison used χ², Fisher’s correlation and Mann–Whitney U tests.

Results 73F, 41M patients were included; average age 60 (range 24–90) with an average FEV1 66% predicted (SD +/−26%). 54 (47%) patients had Pseudomonas isolation; 38 (33%) patients had colonisation. Fatigue levels were similar in patients with and without colonisation (median 44.8 vs 43.5, p=0.31). Significant fatigue (FIS>40) was more common in patients with Pseudomonas isolation (47%) than those with no previous isolates (p=0.04, OR=2.2) However, fatigue levels, although increased, were not significantly different (median FIS 50 vs 32; p=0.064). Fatigue correlated with MMRCD (p=0.34, r=0.0001) but less well with FEV1% predicted (p=0.2, p=0.04). FEV1% predicted was lower in patients with Pseudomonas colonisation (median FEV1 % 49% vs 74%, p=0.0007) and in patients with Pseudomonas isolation (median FEV1 % 52% vs 74%, p=0.002).

Conclusions Pseudomonas infection (past or present) appears to be associated with greater clinically significant fatigue scores and poorer lung function. Fatigue doesn’t strongly correlate with FEV1% predicted but is correlated with MMRCD. Further regression analysis of variables is underway to understand these inter relationships further. Systemic aspects of Pseudomonas infection may be different to other infections explaining the divergence.

AIRWAY DYSFUNCTION AND INFLAMMATION IN POOL AND NON-POOL BASED ELITE ENDURANCE ATHLETES

doi:10.1136/thx.2010.150946.33

1N Martin, 2H R Lindley, 3B Hargaden, 1W Monteiro, 1D Pavard. 1Institute for Lung Health, Glenfield Hospital, Leicester, UK; 2Department Human Sciences, Loughborough University, Loughborough, UK

Introduction Previous studies have suggested that eosinophilic airway inflammation is common in elite swimmers; the chemical pool environment often blamed. We set out to address this question in a cross-sectional study of 109 international athletes from a variety of sporting backgrounds.

Methods All had symptoms suggesting exercise-induced asthma and were either inhaled corticosteroid naïve or withdrew these for >4 weeks. β₂-agonists, exercise and caffeine were withheld for 8 h prior to testing. Symptoms were assessed using the Juniper ACQ, airways dysfunction using the eucapnic voluntary hyperperventilation (EVH) test and airways inflammation using exhaled nitric oxide (FE(NO)) and induced sputum eosinophil % (eos). Athletes were classed as pool based if they exercised in an indoor pool environment for >5 h per week, and non-pool based if they exercised in a pool for <1/2 h per week.

Results Demographic details were similar. Mean (±SEM) % fall in FEV1 post EVH was 15.96±1.701 (n=47) in pool and 11.39±1.249 (n=62) in non-pool athletes (mean difference 7.569; 95% CI 3.480 to 11.66; p=0.0004), 76% of pool and 39% of non-pool athletes had a positive test (>10% fall). The geometric mean (log SD) eos (pool 2.667 (0.797); non-pool 3.060 (0.867), p=0.202), and FE(NO) (pool 25.05 (1.570), non-pool 28.06 (1.475) ppb, p=0.914) was no different between groups; 14% of pool and 12.9% of non-pool athletes had eos >3%. % fall in FEV1 had good correlation with log eos (r=0.551, p<0.0001); a 25% fall being the optimum (AUC 0.912, p<0.0001, sens 78%, spec 92%). Log FE(NO) and log eos correlated strongly (r=0.644, p<0.0001); FE(NO) >47 being most predictive of eos>3% (AUC 0.912, p<0.0001, sens 78%, spec 92%). Symptoms correlated poorly with either airways dysfunction or inflammation.

Conclusions Individual athletes with symptoms vary markedly in the levels of airways dysfunction and inflammation expressed. There is more airways dysfunction in pool athletes but not more eosinophilic airways inflammation suggesting that the pool
