scale and numerical rating scale) were recorded. NRD was expressed as $\text{EMG}_{\text{para}\%\text{max}}$: inspiratory EMG signal normalised to a maximum signal measured during a sniff manoeuvre. The changes in $\text{EMG}_{\text{para}\%\text{max}}$ and IC ($\Delta$IC) between admission and discharge were analysed.

**Results** 31 patients were recruited; only 20 (65%) were able to perform spirometry and IC manoeuvres. The baseline characteristics were 69±11 years; male 55%; body mass index 26.1±7.3 kg/m²; % predicted FEV₁ 63.5±9.3; and 41±24 smoking pack years. The overall mean $\Delta$EMG$_{\text{para}\%\text{max}}$ of the 20 patients fell by 4%, with 16 (80%) patients experiencing a fall in $\text{EMG}_{\text{para}\%\text{max}}$ during their admission. We observed an indirect relationship between $\Delta$EMG$_{\text{para}\%\text{max}}$ and $\Delta$IC ($r=-0.52, p=0.02$), and between $\Delta$EMG$_{\text{para}\%\text{max}}$ and $\Delta$FVC ($r=-0.585, p=0.036$). We found a correlation between $\Delta$IC and $\Delta$FEV₁ ($r=0.658, p=0.015$). There were differences in $\Delta$IC between patients whose $\text{EMG}_{\text{para}\%\text{max}}$ decreased during their admission and those whose $\text{EMG}_{\text{para}\%\text{max}}$ increased (mean difference 0.50 l; $p=0.003$) (Abstract S116 figure 1). There were no significant correlations between dyspnoea scores and $\Delta$IC or $\Delta$EMG$_{\text{para}\%\text{max}}$.

**Conclusion** DH is a significant contributor to NRD in AECOPD. $\Delta$EMG$_{\text{para}\%\text{max}}$ reflects changes in DH during hospital admission, but patient-reported dyspnoea does not indicate the degree of DH, highlighting the limitations of dyspnoea scores. Changes in DH are correlated with changes in airflow obstruction. These data provide a physiological rationale for the utility of parasternal EMG as a non-invasive and non-volitional technique to track clinical change in AECOPD patients.

**S117 RESPIRATORY MUSCLE FATIGUE FOLLOWING EXERCISE IN PATIENTS WITH INTERSTITIAL LUNG DISEASE**

doi:10.1136/thoraxjnl-2011-201054b.117

D Elia, J L Kelly, D Martolini, E Renzoni, A K Boutou, A Chetta, M I Polkey, N S Hopkinson. NIHR Respiratory Biomedical Research Unit of Royal Brompton and Harefield NHS Trust and Imperial College, London, UK

**Background** Patients with interstitial lung disease (ILD) experience progressive breathlessness and exercise limitation. Although respiratory muscle fatigue has been investigated in healthy subjects and patients with COPD, it is unknown whether it occurs during exercise in ILD patients and, if so to what extent it is related to changes in dynamic lung volumes.

**Methods** Patients with ILD performed incremental, symptom-limited cycle ergometry with inspiratory capacity manoeuvres used to measure changes in end-expiratory lung volume (EELV). Twitch transdiaphragmatic pressure (TwPdi), in response to bilateral anterolateral magnetic phrenic nerve stimulation and twitch gastric pressure (TwPga) in response to magnetic stimulation over the 10th thoracic vertebra were used to assess the development of fatigue.

**Results** Sixteen ILD patients (11 women) were studied. TwPdi did not differ significantly pre and post exercise (21.5±8 vs 20.2±8 cmH₂O; $p=0.10$), while TwPga fell from 28.6±18 to 25.2±14 cmH₂O ($p=0.02$) (Abstract S117 figure 1). EELV fell from 2.18±0.651 to 1.91±0.591 following exercise ($p=0.04$). The fall in TwPga correlated with peak VO₂ ($r=-0.52, p=0.041$) increase in heart rate ($r=0.53, p=0.032$) and with the decrease of EELV during exercise ($r=0.57, p=0.021$). Abdominal muscle fatiguers (n=9, 56%), defined as a ≥10% fall in TwPga, had a fall in EELV of 22±22% compared to 0.7±8% in non-fatiguers ($p=0.016$).

**Conclusion** Abdominal muscle fatigue develops during exercise in ILD patients in association with increased expiratory muscle activity manifest by reduced EELV.

**S118 DIRECT VISUALISATION OF COLLATERAL VENTILATION IN COPD WITH HYPERPOLARISED GAS MRI**

doi:10.1136/thoraxjnl-2011-201054b.118

**Introduction and Objectives** Collateral ventilation is important in pathophysiology of Chronic Obstructive Pulmonary Disease (COPD), complicated pneumothorax, and bronchoscopic lung volume reduction surgery but limited observations of it in vivo have been attained. Current techniques capable of imaging collateral ventilation require monitoring over multiple breathing cycles and
