a clinically important QoL improvement and a significantly greater improvement than those treated with NIV. However, the average quality of life of those treated with NIV did not decline by a clinically important amount (table 1).

Conclusions On average, patients hospitalised with AECOPD not requiring NIV experience an improvement in QoL following discharge and in those treated with NIV, QoL does not appear to decline. Most patients can expect their quality of life to be no worse than that reported at hospital discharge.

P83 RELATIONS OF DIFFERENT QUALITY OF LIFE TOOLS TO SUBSEQUENT MORTALITY AND READMISSION OF PATIENTS SURVIVING HOSPITALISATION FOR ACUTE EXACERBATIONS OF COPD

doi:10.1136/thoraxjnl-2012-202678.325

1. Steer, GJ Gibson, SC Bourke. North Tyneside General Hospital, North Shields, United Kingdom; Newcastle University, Newcastle-upon-Tyne, United Kingdom

Background In patients hospitalised with acute exacerbations of COPD (AECOPD), quality of life (QoL) scores have been associated with subsequent mortality and readmission. We have investigated which of several QoL indices are most closely related to subsequent readmission.

Methods 183 patients with AECOPD surviving to hospital discharge were identified prospectively. Baseline clinical information and subsequent mortality and readmission over 12 months were recorded. QoL was assessed at discharge using: the St. George’s Respiratory Questionnaire (SGRQ); the Chronic Respiratory Questionnaire (CRQ); the Hospital Anxiety and Depression Scale (HADS); and the Nottingham Extended Activities of Daily Living Scale (NEADL) and relationships between QoL and each outcome were analysed.

†Lower values indicate improved quality of life; ‡ higher values indicate improved quality of life. SGRQ – St George’s Respiratory Questionnaire; CRQ – Chronic Respiratory Disease Questionnaire; HADS – Hospital Anxiety and Depression Scale; NEADL – Nottingham Extended Activity of Daily Living Scale.

Results Mean (SD) age was 69.0 (9.0) years and most patients: were female (58.5%); had severe airflow obstruction (mean (SD) FEV1, 40.2 (17.3) % predicted); and were of normal weight (mean (SD) BMI 26.2 (7.0) kg/m²). 130 (71%) patients were readmitted during the year following discharge, with a median number of readmissions of 1 (IQR 0 to 3; range 0 to 15). The mortality rates at 3, 6 and 12 months following discharge were 6.6%, 10.4% and 18.0% respectively.

Self-reported measures of activity (SGRQ Activity and NEADL) were the only QoL indices significantly associated with both mortality and readmission. The relations of SGRQ Impacts and HADS Depression to mortality showed nonsignificant trends, but no other QoL domains were associated with readmission (table 1).

Conclusion Measures of self-reported activity at discharge were the most closely associated with both subsequent mortality and readmission and are likely to be the most useful of the QoL indices studied for predicting clinical outcome.

P84 UTILITY VALUES FOR COPD PATIENTS BASED ON THE EQ-5D QUESTIONNAIRE FROM THREE INDACATEROL PHASE III STUDIES

doi:10.1136/thoraxjnl-2012-202678.326

1. Y Asukai, M Baldwin, L Mungapen. `iMS Health Economics and Outcomes Research, London, United Kingdom; Novartis Pharmaceuticals, Horsham, United Kingdom

Introduction and Objectives Chronic obstructive pulmonary disease (COPD) is characterised by airflow limitation that is not fully reversible and disabling symptoms such as breathlessness and COPD exacerbations, which have a negative impact on health-related quality of life (HRQoL). The indacaterol clinical trial programme (INVOLVE, INHANCE and INLIGHT-2 trials) collected HRQoL using the EuroQol (EQ-5D) instrument, a commonly used tool to generate preference-based utilities involving five dimensions of a health state. As part of the clinical trial programme, the EQ-5D scores were converted to a utility index score using the UK National Health Survey (1) preference weights. The aim of this analysis was to report mean utilities of COPD patients by disease severity.

Methods A total of 11,066 observations from three trials were included in the analysis. Utility index scores were summarised by disease severity (GOLD 2008 FEV1-based) to yield a mean utility weight for each disease severity class. Disease severity was determined by using all available FEV1 readings. Since some trials had a longer duration contributing more records of EQ-5D and spirometry than others, it was necessary to correct for multiple observations; utility values that might have been derived from the shorter-duration trials were considered as ‘missing’ data. To impute
missing data, a mixed effects model was used using residual maximum
likelihood. Clinic visit and disease severity were included as
factors. Utility values were assumed to be missing at random.
Results The estimated utility of COPD patients according to levels
of disease severity was as follows: Mild = 0.820 (95% CI: 0.800–
0.840); Moderate = 0.801 (95% CI: 0.794–0.809); Severe = 0.774
(95% CI: 0.767–0.782); and Very Severe = 0.743 (95% CI: 0.730–
0.756). The correlation between increasing disease severity and
decreasing patients’ utility demonstrated the internal validity of the
data.
Conclusion This analysis provides estimates of utility by COPD
disease severity based on one of the largest sample sizes used to
date, which is essential for cost-utility analyses that help inform
healthcare decisions.

P85 ASSESSING THE PATIENT EXPERIENCE OF COPD CARE USING AN IPSOS MORI QUESTIONNAIRE AS A PATIENT REPORTED EXPERIENCE MEASURE (PREM)
doi:10.1136/thoraxjnl-2012-202678.327

1DJ Prowie, 'M Ali, 'S Ansari, 'KG Lingam, 'P Mulley, 'S Hope, 'AG Davison. 'Southend University Hospital, Westcliff on Sea, UK; 'GlaxoSmithKline, Stackley Park West, UK; 'Ipsos MORI, London, UK

Patient reported experience measures provide vital information on
the experience that patients have regarding their care and thus have
become a recent focus of interest. We have developed a question‑
naire to assess PREMs in patients with COPD attending a hospital
outpatient clinic. The purpose of the questionnaire was to assess
whether the processes that are necessary to improve outcomes in
COPD had been dealt with in the clinic and understood by the
patient. Also to assess in a similar way the understanding of COPD
by the patient and whether they were satisfied with the consultation.

Results The questionnaire was completed by 142 new and follow‑
up patients. Results are presented in the table below. 92% of patients
had spirometry performed at their visit and 78% had the results
explained. Before the consultation 57% of patients thought they
had a good understanding, 30% moderate and 13% little or no
understanding of their condition. Afterwards these improved to
67%,23% and 10% respectively. 29% believed that their knowledge
of how to reduce exacerbations had increased after the consultation.
87% of patients thought that the length of the review was about
right (average 20 minutes). 85% were satisfied overall with the
consultation.

Conclusion We have studied COPD care from the patient’s per‑
spective. We have found evidence that simple clinician-led measures
(such as flu vaccination and spirometry) have been explained either
clinic or previously and understood by the patient. We were less
successful in dealing with more complex patient-centred experiences
such as understanding of the disease and self management of ex‑
acerbations. Following this study we plan to develop a questionnaire
dealing with the patient’s understanding of their disease that would
be filled in before attending clinic. This would allow areas of con‑
cern to the patient to be specifically addressed in the consultation.
In addition the questionnaire could be used to provide feedback to
individual clinicians on their effectiveness in outpatient clinics.

Cystic Fibrosis: diagnosis to therapy

P86 THE SCREENING AND DIAGNOSIS OF CYSTIC FIBROSIS‑
RELATED DIABETES IN THE UNITED KINGDOM
doi:10.1136/thoraxjnl-2012-202678.328

1KL Wickens-Mitchell, 1FJ Gilchrist, 1W Lenney, 1Keele University, Keele, UK; 2University Hospital of North Staffordshire, Stoke on Trent, UK

Introduction Cystic fibrosis related diabetes (CFRD) affects 17%
of CF patients in the UK and is increasing in prevalence. It has a
major detrimental impact on pulmonary function, nutritional sta‑
thus and survival; these effects are frequently seen prior to diagnosis.
The UK CF Trust guidelines regarding CFRD screening, diagnosis
and management differ from those used in Europe and the USA. We
conducted a study to establish current UK clinical practise.

Methods A questionnaire was emailed to consultants at each of
the 48 UK CF specialist centres. Data were gathered on the screening
and diagnosis of CFRD as well as the personnel involved.

Results Completed questionnaires were returned by 39/48 centres
(81%). Only 3/21 (14%) paediatric centres begin screening at 12 years
(as per the UK CF Trust guidelines), with the majority; 11/21
(52%) starting to screen children at 10 years (as per the European and
USA guidelines). Five centres start screening at a child’s first annual
review. The most common test used to screen patients for CFRD is
the oral glucose tolerance test (OGTT) which is used in 35/39 (85%)
centres. However, this tool is only used in isolation by 3/38 (9%) centres.
More commonly, results of the OGTT are combined with random blood glucose tests and/or HbA1c measurement. The test most frequently used to diagnose CFRD is home blood glucose mon‑
itoring which is undertaken in 32/39 centres (82%). Again this is
rarely used in isolation, more commonly combined with HbA1c and/or
with the results of a continuous glucose monitoring system
(CGMS). CGMS is undertaken for diagnosis in 25/39 centres (59%).
The decision to initiate insulin therapy was most often shared
between a CF consultant and diabetologist. However, in 4/14 (26%)
centres a diabetic nurse specialist had sole responsibility.

Conclusions In UK clinical practise the screening and diagnosis of
CFRD is not uniform. Various methods are used and there is poor
adherence to UK CF Trust guidelines. However, these guidelines from
2004 are somewhat out-dated and need to be updated to reflect the current best available evidence. This is likely to decrease
the variation in practise.

P87 THE IMPACT OF RESPIRATORY VIRUSES AND PULMONARY
EXACERBATIONS ON FEV1 DECLINE IN ADULTS WITH
CYSTIC FIBROSIS
doi:10.1136/thoraxjnl-2012-202678.329

1WG Flight, 1KJ Mutton, 1AK Webb, 1RJ Bright-Thomas, 1AM Jones. 1Manchester Adult Cystic Fibrosis Centre, Manchester, United Kingdom; 2Dept of Virology, Manchester Royal Infirmary, Manchester, United Kingdom

Introduction Viral respiratory infection (VRI) is associated with
an increased rate of decline in lung function in children with cystic
fibrosis (CF) but the long-term clinical impact of VRI in adults is
poorly described. We performed a prospective observational study
to determine the effect of VRI on lung function in adults with CF.

Methods 100 adults with CF were followed for 12 months.
Patients were seen every two months routinely and also at onset of
new respiratory symptoms. Sputum, nose- and throat-swabs were
