Impact of morning symptoms experienced by COPD patients on exacerbation risk, rescue inhaler usage and normal daily activities

**Methods**
Data were drawn from a real world study of consulting COPD patients in the USA and Europe in 2011. Results were tested for significance (p<0.05) using Mann-Whitney and negative binomial regressions. Confounders included age, gender, BMI, comorbidities, severity, smoking status and adherence.

**Results**
Of the 3790 patients in the study, 593 were receiving ICS/LABA-only (+/- rescue). Of the 177 patients reported to experience morning symptoms, cough (65.5%) and excess sputum (53.1%) were the most common. Compared with patients without morning symptoms, these patients were associated with higher mean exacerbation frequency in the last 12 months (1.04 vs 0.63 p<0.001), rescue usage per day (0.58 vs 0.46 p=0.025) and daytime impact on a 7-point Likert scale where 7 represents a constant impact (3.61 vs 3.00 p<0.001).

**Conclusion**
Morning symptoms were associated with significantly more impaired breathing control for patients treated with ICS/LABA-only therapy. The association implies morning symptoms are an important indicator when assessing the impact of COPD and their presence suggests that further therapeutic intervention may be necessary.

**P209** IMPACT OF PATIENT SATISFACTION WITH THEIR MAINTENANCE INHALER ON TREATMENT COMPLIANCE AND HEALTH OUTCOMES IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE: AN ANALYSIS OF REAL-WORLD CLINICAL PRACTICE IN EUROPE

**Methods**
Data were analysed from a large, cross-sectional survey of real-world clinical practise conducted in five European countries. Respiratory specialists and primary care physicians provided information on six consecutive patients with COPD (aged ≥40 years with history of smoking). The same patients were then asked to voluntarily complete a self-assessment form. Physicians scored patient compliance with prescribing instructions (5-point Likert scale: 1=’not at all compliant’, 5=’fully compliant’). In each question, patients rated overall satisfaction with their maintenance inhaler (7-point Likert scale: 1=’not at all satisfied’, 7=’very satisfied’). Health outcomes included exacerbations, the modified Medical Research Council dyspnoea scale, the EuroQol (EQ-5D) instrument and the Jenkins Sleep Questionnaire. Sequential regression was used to analyze the relationship between inhaler attributes and overall satisfaction. Least-squares regression and additive models were used to analyze the relationships between inhaler satisfaction, compliance and health outcomes.

**Results**
Data were included for 1443 patients for whom self-completed and matched physician-completed record forms were available. The majority of patients (71.8%) were male; mean age was 65.2 years. Very few patients (0.7%) were ‘not at all compliant’ with their physician’s prescribing instructions, whilst 33.3% were ‘fully compliant’. Most patients (75.1%) were more satisfied with their inhaler than not; 6.6% were ‘very satisfied’. Key attributes influencing satisfaction related to durability, ergonomics and ease of use. There was a significant association between inhaler satisfaction and compliance (χ² – df=89.7; p<0.001). Other factors related to greater compliance, though to a lesser degree, were fewer maintenance drugs (χ² – df=17.7; p<0.001) and male gender (χ² – df=2.9; p<0.05). Severity of breathlessness, age and ethnicity were not significantly associated with compliance (p>0.05). Higher compliance scores were significantly associated with better health outcomes (Table). There was also a direct association between inhaler satisfaction and better health outcomes (exacerbations and EQ-5D, p<0.001).

**Conclusions**
Inhaler satisfaction appears to be significantly associated with COPD treatment compliance, and patients with greater compliance experience better health outcomes, including less frequent exacerbations.

**P210** ARE SPUTUM AND BLOOD BIOMARKERS OF INFLAMMATION REPEATABLE IN STABLE COPD?

**Background**
Spirometry is a commonly used end-point in COPD clinical trials and there is evidence that spirometric values are reproducible in COPD patients. COPD is heterogeneous and differences in biomarkers of pulmonary and systemic inflammation between patients can be identified. Currently limited short-term reproducibility is available in stable COPD.

**Aims**
Assess repeatability of commonly used clinical measures in subjects with stable COPD over 3 and 6 months.

**Methods**
Subjects with COPD were enrolled into an observational study and were reviewed at stable visits after 3 and 6 months. Spirometry, blood [nadir peripheral blood total white cell and differential cell counts] and sputum [sputum differential cell counts (%)] markers of inflammation were repeated at each visit. Repeatability of
