syndecan-1 expression. These questions are the subject of ongoing studies into the role of RAGE activation in endothelial dysfunction in SIRS.

**S73** CIRCULATING REGULATORS OF ACUTE MUSCLE WASTING IN THE CRITICALLY ILL: GDF-15 A POTENTIAL NOVEL DRIVER OF ACUTE MUSCLE WASTING

doi:10.1136/thoraxjnl-2012-202678.079

**Introduction** Acute muscle wasting in the critically ill manifesting as intensive care unit acquired paresis (ICUAP) is common, and causes significant morbidity and mortality. The pathological mechanisms underlying ICUAP are poorly understood and, other than rehabilitation, no therapeutic interventions exist. It was hypothesised that known or potential circulating modulators of muscle mass: insulin-like growth factor-1 (IGF-1), myostatin and growth and differentiation factor-15 (GDF-15) would have distinct dynamic profiles in patients who develop acute muscle wasting in a novel human model of ICUAP.

**Methods** In a prospective observational study of 42 patients undergoing elective high-risk cardiothoracic surgery (at the Royal Brompton Hospital, London, UK) those who developed muscle wasting were identified by ultrasound. Circulating IGF-1, myostatin and GDF-15 were assayed pre-operatively and over the first week post-operatively. The ability of GDF-15 to cause muscle wasting in vitro was determined in cultured C2C12 myotubes.

**Main results** 23 of 42 patients (55%) developed quadriceps atrophy. Plasma concentrations of IGF-1 and unexpectedly myostatin, known mediators of muscle hypertrophy and atrophy respectively, both decreased from baseline in the first post operative days. By contrast, plasma GDF-15 concentrations increased in all patients. This increase in GDF-15 was higher (535±308% versus 495±247%) and sustained at day 7 in those who developed muscle wasting (day 7 compared with baseline, p<0.01), but recovered in the non-wasting group (p>0.05). Furthermore IGF-1 also did not recover in those who developed muscle wasting (day 7 compared with baseline, p<0.01) but did in the non-wasting group (p>0.05). Myostatin recovered to baseline in both groups. Finally, we demonstrated that GDF-15 caused atrophy of myotubes in vitro (average control myotube diameter was 26.3±9.0 µm versus 22.3±7.5 µm for GDF-15 treated myotubes, equating to 15% myotube atrophy, p= 0.011).

**Conclusion** This data supports the hypothesis that acute muscle loss occurs as a result of an imbalance between drivers of muscle atrophy and hypertrophy. GDF-15 is a potential novel mediator of muscle atrophy in ICUAP, which may become a therapeutic target in patients with ICUAP and other forms of acute muscle wasting.
liver function tests. Patients with central line placement and hepatica exposure were associated strongly with mild thrombocytopenia (p<0.0001). Drug therapies that were correlated with thrombocytopenia included Heparin, Protonix, Lasix, Ativan and Zofran and antibiotics such as Vancomycin, Cephalosporins and Levquin.

**Conclusion** Drug regimens should be evaluated daily for minimization of adverse drug events including thrombocytopenia. Once the diagnosis is suspected, clinicians should identify the medication and/or risk factors causing secondary thrombocytopenia to assess the timeline of development. Co morbidity associated with thrombocytopenia was sepsis syndrome, liver disorder, alcoholism and atrial fibrillation. Medications commonly associated with drug-induced thrombocytopenia include glycoprotein IIb/IIIa inhibitors, cinchona alkaloids, antibiotics, anticonvulsants, and heparin. Thrombocytopenia generally resolved in most patients with critical management of the disease and discontinuation of the offending medication.

**S75** HIGH DOSE VITAMIN D SUPPLEMENTATION IMPROVES EXTRAVASCULAR LUNG WATER INDEX AND IN-VIVO TREG AND LL37 RESPONSES POST-OESOPHAGECTOMY

doi:10.1136/thoraxjnl-2012-202678.081

1RCA Dancer, 1D Parekh, 1AR Martineau, 1GD Perkins, 1DR Thickett. University of Birmingham, Birmingham, UK; 2BartsThe London School of Medicine and Dentistry, London, UK; 3Warwick Medical School, Coventry, UK

Acute Lung Injury occurs in around 25% of patients post 2 stage oesophagectomy. We have previously shown that levels of 25-OH vitamin D are low in these patients and that those patients with the lowest levels of vitamin D are more likely to develop Acute Lung Injury post-operatively. In vitro, vitamin D has been shown to promote the differentiation of regulatory T cells (Treg) and the expression of LL37 (cathelicidin), an antimicrobial peptide.

We have given 13 patients a one-off high dose vitamin D supplement 3–14 days prior to oesophagectomy. Numbers of circulating regulatory T cells were analysed both pre- and post-supplementation. Plasma levels of LL37 were measured by ELISA. Extravascular Lung Water Index (EVLWi) was measured pre-operatively, post-operatively and on the day following surgery. Changes in LL37 and EVLWi were compared with results from a cohort of patients (n=50) who had not been supplemented.

Pre-operative vitamin D levels between the two groups were significantly different. The proportion of CD3+CD4+ T cells which were CD25+CD127loFoxP3+ increased post vitamin D supplementation (median pre vitamin D=5.8, median post vitamin D=7.3, p=0.028). Whilst levels of LL37 decreased post-operatively in the cohort who had not received vitamin D, levels were maintained in supplemented patients. Post-operative EVLWi measured lower than pre-operative values in patients receiving vitamin D supplementation. This contrasts with patients who did not receive vitamin D supplementation in whom an increase in EVLWi was seen. This difference persists on post-operative day 1, with a net increase being seen in patients who did not receive vitamin D and a net decrease in those who did (see table).

**Conclusions** A stat high dose vitamin D supplement restored vitamin D levels in the week before oesophagectomy. This was associated with elevated circulating Treg levels in vivo and an increase in post-operative plasma LL37 expression suggesting the vitamin D supplementation was biologically active.

**Patients** receiving vitamin D had no perioperative increase in extravascular lung water compared to our historical cohort suggesting that vitamin D protects against alveolar epithelial damage perhaps in part due to effects on circulating Treg cells and anti-microbial peptide production.

**S76 PROTEOLYTIC CLEAVAGE OF ELAFIN BY 20S PROTEASOME MAY CONTRIBUTE TO INFLAMMATION IN ACUTE LUNG INJURY**

doi:10.1136/thoraxjnl-2012-202678.082

1A Kerrin, 1S Weldon, 1A Chang, 1T Craig, 1AJ Simpson, 1C O’Kane, 1DF McAuley, 1C Taggart. Queen’s. University Belfast, Belfast, United Kingdom; 2National Institutes of Health, Bethesda, USA; 3University of Newcastle, Newcastle, united Kingdom

The **Aim** of this study was to characterise temporal changes in elafin concentration in patients with acute lung injury (ALI) and to evaluate whether a decrease in elafin levels is due to elevated protease activity. Previous work has shown that unregulated protease activity can cause proteolytic cleavage of elafin, impairing the innate immune function of the protein. Bronchoalveolar lavage fluid (BALF) was obtained from patients with ALI within 48 hours of onset of ALI (day 0), at day 3 and at day 7. Elafin levels were quantified by ELISA. Elafin susceptibility to proteolytic cleavage by ALI BALF was assessed by Western blot and by HPLC-Mass Spectrometry. Elafin levels were found to be significantly increased at the onset of ALI compared to healthy volunteers and fell significantly by day 7 compared to day 0. In contrast, levels of secretory leukocyte protease inhibitor (SLPI) did not decrease over time. This decrease in elafin was due to cleavage by the 20S proteasome which was significantly increased in ALI BALF. Incubation of BALF with the proteasome inhibitor epoxomicin confirmed that 20S proteasome protease activity was responsible for proteolytic cleavage of elafin resulting in diminished anti-elastase activity. In addition, free neutrophil elastase (NE) activity significantly increased in BALF from day 0 to day 7. In conclusion, elafin concentrations decrease within the pulmonary compartment over the course of ALI as a result of proteolytic degradation. This loss of elafin may predispose, in part, to excessive inflammation in ALI.

**S77 PRONE POSITIONING AND INTRAVENOUS STEROIDS FOR THE MANAGEMENT OF SEVERE ARDS**

doi:10.1136/thoraxjnl-2012-202678.083

L Gupta, Ben SiuJames. Regional Medical Center of San Jose, San Jose, USA

**Introduction** Prone positioning and intravenous steroids represent a treatment option in patients with severe ARDS because most of the clinical manifestations in ARDS is secondary to excess fluid in the interstitium and alveoli and presence of inflammatory cells in the fluid.

**Objective** To assess the impact of prone positioning and steroids in severe ARDS and to assess and identify prognostic factors and potential predictors of mortality in ARDS patients.

**Methods** This is a retrospective study of 46 patients with severe ARDS from 2009–2011. The patient charts were reviewed and the impact of prone positioning and steroids was observed on severe ARDS patients. The primary outcome measured were ICU length of stay, number of ventilator days and 30 day mortality.
