Amoxicillin-clavulanate for chronic wet cough in children: cautious interpretation of study findings warranted

We read with interest the recent paper by Marchant *et al* comparing amoxicillin-clavulanate to placebo for the treatment of chronic wet cough in children.¹ The authors should be commended for attempting a randomised controlled clinical trial in this group of patients that often present paediatricians with a management dilemma. Nevertheless, we have significant concerns regarding several aspects of the study methodology, analysis and interpretation and feel that the authors have overstated their conclusions. We therefore urge caution in interpretation of the study findings.

First, the definition of chronic cough used in the study (greater than 3 weeks) contradicts the authors' previously recommended definition of 4 weeks.² Second, for their primary outcome, the authors used improvement in 'baseline cough score' based on 'validated cough diary using the

verbal category descriptive (VCD) score'. While this statement is true, the VCD score has only been validated in children aged 6 years or older and when completed by the child,³ important considering few patients older than 6 years of age were recruited. Third, cough 'resolution' was defined as a reduction of 75% in the VCD score from baseline. We question the use of a median (IQR) VCD score on a scale that contains six categories. We feel it would have been preferable to report the proportion of patients with cough resolution in each VCD score category within the two groups. In Table 1 of the manuscript, it can be seen that the baseline 75th centile VCD score in both groups was 3.0. This would indicate that children whose VCD score was greater than 0.5 at study endpoint, despite significant improvement in their symptoms, would still be classified as a failure based on the primary outcome. Fourth, given the relatively long period of time that elapsed between patient recruitment and subsequent publication, it would have been interesting to know the long-term outcomes of the children. Finally, although beyond the scope of the current study, the potential impact of prolonged antibiotic treatment in selecting out resistant organisms should not be discounted.

Despite the shortcoming to the study by Marchant *et al* that preclude definitive conclusions, we believe it represents a valuable contribution to the literature in this challenging area. We eagerly await the results of future, adequately powered studies with more robust study endpoints to provide the definitive evidence to determine the true role of antibiotics in children with chronic wet cough.
