Efficacy and Safety of Omalizumab in Real-World Clinical Practice in Indian Patients with Allergic (IgE-Mediated) Asthma: Analysis by Baseline Severity of Asthma

Omalizumab (OMA) is a humanised anti-immunoglobulin E (IgE) monoclonal antibody, indicated as add-on therapy for moderate-to-severe persistent allergic (IgE-mediated) asthma. Here, we report the interim results of a 52-week observational study of OMA in patients in India, stratified by baseline severity of asthma.

In this open-label, non-comparative, non-interventional study, patients (age = 12 years) with moderate-to-severe persistent allergic asthma, inadequately controlled despite ICS + LABA (GINA step 4) treatment, were recruited. All patients were receiving OMA at baseline. Outcomes were assessed every 4 weeks, and included exacerbations, days missed at college or work, hospitalizations, and mean change in ACQ5 score (composite) and ACT score versus baseline. Adverse events were also recorded. Asthma severity was assessed at baseline, in accordance with GINA guidelines, and classified as either moderate (group 1) or severe (group 2). Data were analysed using chi-squared and paired t-tests. All parameters were compared between baseline and Week 28 post-OMA treatment.

To date, 100 patients have completed 28 weeks of follow-up (36 patients in group 1 and 64 in group 2). Results are presented in the Table. The proportion of patients with exacerbation, missing any day at work or college, or requiring hospitalisation decreased appreciably in both groups. There was also significant improvement in lung function and asthma control, and a reduction in OCS need. Overall, 5 patients (5%) reported adverse events (AEs), of whom 2 (2%) reported serious AEs (SAEs). The most frequent non-serious AEs were gastrointestinal (GI) and nervous system disorders and were suspected to be related to omalizumab. GI, respiratory, and mediastinal SAEs were reported, but were not suspected to be related to omalizumab. All reported AEs and SAEs resolved with treatment.

Results: 15 patients were randomised to receive both high- and low-dose FP/FORM. The change in AMP PD20 FEV1 was greater with FP/FORM high- compared with low-dose (LS mean: 2.4; 95% CI 1.3, 4.5; p = 0.012). FP/FORM was well-tolerated; only few (mild or moderate) AEs occurred.

Conclusions: A significant dose-response was found between low- and high-dose FP/FORM with the higher dose demonstrating a greater reduction in airway responsiveness to AMP.

P168 The Effect of Fluticasone Propionate/Formoterol Fumarate Combination Therapy on Quality of Life Scores in Asthma Patients

Introduction: The Asthma Quality of Life Questionnaire (AQLQ) is a validated questionnaire which measures the effect of asthma on patient’s lives. AQLQ data from four phase III studies were pooled to assess how AQLQ scores are affected by treatment with fluticasone propionate (FP)/formoterol fumarate (FORM) in a single MDI (FP/FORM; doubleinhaler) compared with other combination treatments.

Method: AQLQ data from a pooled analysis of two phase III open-label studies in patients with mild-moderate/severe asthma [pool 1; FP/FORM 250/10 (n = 294) vs. FP 250 + FORM 12 (n = 294)] were presented. AQLQ scores range from 1–7; a low score indicates the most severe impairment. Change in AQLQ score from baseline to end of study was analysed using an ANCOVA.

Results: In pool 1, both groups had a similar increase in overall AQLQ score from baseline to end of study (0.635 in the FP/FORM group and 0.771 in the combination group) and the percentage of patients with a clinically relevant change in overall AQLQ score was 56% and 59%, respectively. In pool 2, the mean increase in overall AQLQ score from baseline to end of study was 0.837 in the FP/
FORM group and 0.756 in the combination group, with 58% and 56% of patients experiencing a clinically relevant change in overall AQLQ score, respectively. The difference between the groups in each analysis was not statistically significant.

**Conclusion** FP/FORM has a similar effect on the quality of life of asthma patients as other combination treatments, with a similar improvement shown in each treatment group for both pools. Over 50% of patients in both treatment groups showed a clinically relevant change in AQLQ from baseline to end of study.

**Rationale** Given the known effectiveness of tiotropium in chronic obstructive pulmonary disease (COPD) and the significant benefit observed in COPD patients with concomitant features of asthma, it is relevant to investigate whether patients included in the recent large trials of tiotropium in asthma can be confidently considered to have asthma alone.

**Methods** Baseline characteristics were analysed for patients enrolled in two replicate Phase III, randomised, double-blind, placebo-controlled, parallel-group studies of tiotropium in asthma patients symptomatic despite treatment with inhaled corticosteroids plus long-acting beta agonists (Kerstjens et al. *NEJM* 2012). The entry criteria were: age: 18–75 years; asthma diagnosed before the age of 40 years; ≥5-year history of asthma; score of ≥1.5 in the Asthma Control Questionnaire (ACQ) ≥7; and life-long non-smokers or ex-smokers (<10 pack-years). Patients were also required to have persistent airflow limitation. Asthma diagnosis was confirmed in line with current Global Initiative for Asthma guidelines. Patients with a diagnosis of COPD or other lung disease were excluded from the studies.

**Results** 912 patients were enrolled: 456 received add-on treatment with tiotropium and 456 received placebo. Mean age of the study population was 53.0 years; 37.6% of patients were aged ≥50 years. Mean age at diagnosis of asthma was 22.7 (range 0–44) years. Median duration of asthma was 28.0 (range 5–72) years, with 76.3% of patients having asthma for ≥20 years before enrolment. The majority of patients (75.9%) were life-long non-smokers; 24.1% were ex-smokers with a median number of pack-years of only 5.0. Mean ACQ score was 2.6 (range 1–5). Mean immunoglobulin E was 1210 μmol/L. The mean (± SD) bronchodilator response to salbutamol was 217 ± 217 mL.

**Conclusions** The age of onset, duration of symptoms, lack of smoking, allergic status and bronchodilator response provide reasonable certainty that the patients enrolled in these studies had asthma and not COPD. Features compatible with COPD were thus more likely to reflect the effects of long-standing severe persistent asthma than the alternative diagnosis, and the efficacy demonstrated by tiotropium to represent improvement of asthma.

**Long-Term Effectiveness of Omalizumab in Patients with Severe Persistent Allergic (IgE-Mediated) Asthma: UK Centre Real-Life Experience**

*1AH Mansur, 1Y Mitchell, 1L Alfdi, 1L Sullivan, 1Y Kacuer; 1Severe & Brittle Asthma Unit, Birmingham Heartlands Hospital, Birmingham, UK; 2Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, UK*

10.1136/thoraxjnl-2013-204457.321

Omalizumab has been shown to be an effective add-on therapy for patients with uncontrolled severe persistent allergic (IgE-mediated) asthma. There has been a steady accumulation of evidence on long-term effectiveness of omalizumab; however, data on real-life outcomes beyond one year of treatment in a UK clinical setting is limited. In this analysis, data were compared for a number of patients from the Heartlands Hospital (Birmingham, UK), to determine if improvements were sustained with longer-term treatment. Patients (n = 45, mean age 44.9 years, range: 19–69) received omalizumab for a mean duration of 49.3 months (range: 23–96). All patients with available data (n = 18/45) showed a clinically relevant improvement in asthma control questionnaire (ACQ) scores post-omalizumab (mean ΔACQ: 2.27, range: 0.5–4.1; mean baseline ACQ: 4.1, range: 3.7–4.7). In patients on oral corticosteroids (OCS) vs patients not on OCS (at baseline), improvements were greater: ACQ of patients on OCS at baseline was 4.1 and 1.6 post treatment vs 4.0 at baseline and 2.7 post treatment. Mean OCS dose reduced pre- to post-omalizumab: 30.5 to 7 mg/day. Reductions in hospital admissions/bed days were seen post-treatment (figure). There were also reductions in work/school days missed in 17/19 patients; the other 2 patients showing no change. Overall mean FEV₁ was improved in the majority of patients with available data (17/20). Results from this real-life follow-up study demonstrate that improved outcomes in patients with severe allergic asthma are sustained with longer-term omalizumab therapy.
