PRE-TRANSPLANT C-REACTIVE PROTEIN (CRP) AS A MARKER OF POST-TRANSPLANT OUTCOMES IN PATIENTS WITH CYSTIC FIBROSIS (CF)

A Fazleen, J Parmar. Papworth Hospital NHS Foundation Trust, Cambridge, UK

10.1136/thoraxjnl-2016-209333.243

**Introduction**

Although novel therapies for CF have been introduced, the condition still has a high rate of complications and early death. Transplantation remains the only hope for extended survival and quality of life. Our study aimed to determine whether pre-transplantation CRP could predict outcomes post-transplantation.

**Methods**

In a retrospective analysis of all lung transplantations performed at our centre between 2001 and 2016, only patients who had complete data were analysed. CRP levels within 72 hours pre-transplantation were compared with length of intubation, ITU and hospital stay, Primary Graft Dysfunction (PGD), pulmonary infection within 3 months post-transplantation and rates of acute cellular rejection.

**Results**

Among 100 patients who underwent lung or heart/lung transplantation, 72 patients had a complete dataset. Average age at transplantation was 28.1 in both groups.

48 patients had CRP < 40 mg/L (24 males, 24 females, median CRP 14), and 24 patients had CRP > 40 mg/L (14 males, 10 females, median CRP 60). Average age of donor was 41.6 in the low CRP group, and 41.8 in the high CRP group.

Average duration of intubation was 66.7 hours in the low CRP group, versus 48.0 hours in the high CRP group, while average length of ITU stay was 6.9 days in the low CRP group, versus 9.3 days in the high CRP group (p 0.76). Average duration of hospital stay was 26.3 days in the low CRP group, and 25.7 days in the high CRP group. Mean number of infections in the low CRP group was 2.4, and 3.3 in the high CRP group (p 0.36).

Kaplan-Meier plots showed no evidence of impact on survival to 5 years.

**Conclusion**

CRP within 72 hours pre-transplantation in patients with CF was not a predictor of short- or long-term outcomes in our study. It is important to note that the sample size for this study was quite small, possibly contributing to this finding. Extension of this study to include patients from multiple transplant centres would be beneficial.

STRUCTURED HOLISTIC NURSING ASSESSMENT (HNA) IN BUCKINGHAMSHIRE HEALTHCARE TRUST (BHT) FOR LUNG CANCER & MESOTHELIOMA PATIENTS: PROCESS AND FINDINGS

J Mowforth, H Steiner, A Prasad. Buckinghamshire Healthcare NHS Trust, Aylesbury, UK

10.1136/thoraxjnl-2016-209333.244

**Aim**

Lung cancer and mesothelioma patients have complex needs. Without a structured process of screening and assessment these can go undetected. Structured screening and assessment needs considered planning. Our experience of screening and assessment of the holistic needs for lung cancer and mesothelioma patients in BHT is described.

**Method**

All BHT lung cancer and mesothelioma patients are invited to be screened post diagnosis using the Distress Thermometer and Needs checklist (Brennan et al 2012). Participation...
rates vary between 55–65% and since 2013, 467 patients have been contacted with 265 patients participating. A database stores all HNA activity. This includes individual overall numerical score for distress (0–10), a breakdown of categories of need including physical, emotional, practical, social and spiritual. It also records specific aspects of distress within each category and where specified the top four aspects of need.

Results Of the 265 respondents, 196 (74%) recorded physical problems, 145 (54%) recorded emotional issues with worry, fear, sadness and depression siting as the top four aspects. In addition 63 (24%) reported practical problems e.g. money and transport, 53 (20%) family problems, and 32 (12%) spiritual concerns. Overall tiredness, breathing, getting around and worry are the top four needs recorded by our patients. Of all patients screened to date a third score Distress above 5, these patients are prioritised for a nurse led clinic.

Conclusion Through screening issues often not disclosed in doctor led clinics are identified and addressed leading to involvement of other professionals and services. Screening patients away from the clinical setting enables greater disclosure, prevents bias or influence on scoring and allows complex needs that might go undetected to be explored. The process enables care to be patient focused and proactive in managing complex needs before crisis events occur.
