Results mutually adjusted for all the patient features in the table

The results of logistic regression from date of procedure to 90 days, 6 months, one year and 2 years in patients who were less than 80 years, PS 0 or 1 and stage IA are presented in S1 table. Overall, patients undergoing SABR were 2 times more likely to die after procedure which was only significant at 95% CI. There was no difference between the two groups at 90 days, 6 months and one year after the procedure by age, charlson index, pathologically confirmed diagnosis, laterality and affluent socioeconomic groups. Male sex, PS 1 and most deprived socioeconomic status were the only three characteristics that were significant at 99% confidence interval.

Table S2: Regression analysis from date of diagnosis till death at 90 days, 6 months, one year and overall in patients aged <80 years, PS 0 or 1 and stage IA only

	Total number of patients	Adjusted odds ratio at 90 days after procedure (95% CI)	Adjusted odds ratio at 180 days after procedure (95% CI)	Adjusted odds ratio at 365 days after procedure (95% CI)	Adjusted odd ratios at 730 days after procedure (95% CI)‡
