pro-fibrotic mediator TGF-β1, plays a critical role in the pathogenesis of Idiopathic Pulmonary Fibrosis (IPF). Both galectin-1 and galectin-3 potentiate this TGF-β1 signaling pathway to promote fibrogenesis, although the exact mechanism is unclear. Integrins are glycoproteins thus their activity can be facilitated by glycan-mediated interactions with N-linked glycosylation the most well studied.\(^1\)

**Objective** To investigate whether galectin-1 and galectin-3 interact directly with αβ1, αβ5 and αβ6 integrins using biophysical methods.

**Methods** Integrin-galectin interactions were determined by surface plasmon resonance (SPR) in the presence of divalent cations and the effect of extensive integrin deglycosylation or removal of N-linked oligosaccharides alone explored. SPR was used to assess integrin-galectin interactions in the presence of small molecule galectin inhibitors, GB1107 (galectin-3 selective inhibitor) or GB1490 (galectin-1 selective inhibitor). Binding of both galectins to N-Acetyl-D-glucosamine was assessed by isothermal titration calorimetry (ITC).

**Results** SPR data showed that both galectin-1 and galectin-3 bind to recombinant human αβ1, αβ5 and αβ6 in a glycosylation-dependent manner. Minimal integrin-galectin binding was observed following integrin protein deglycosylation or in the presence of small molecule galectin inhibitors which act via the galectin carbohydrate binding domain (CBD). However, the removal of integrin N-linked oligosaccharides alone resulted in only a partial decrease in integrin-galectin binding. Additionally, ITC demonstrated that both galectin-1 and galectin-3 were unable to bind N-Acetyl-D-glucosamine; the αβ1 terminal sugar required for αβ1-fibronectin binding.

**Conclusion** Galectins are able to bind to integrins via their post-translational glycosylation sites. Collectively, these data suggest that the presence of both N-linked and O-linked glycan residues are essential for integrin-galectin binding, and that this binding may occur at the galectin galactoside-binding pocket. Understanding the precise role of galectins in integrin-mediated TGF-β1 activation and IPF pathogenesis may be critical for the continued development of more effective and selective treatments for IPF patients.

The mesothelium is a serous membrane lining of the coelomic cavities, which comprise the pleura, pericardium, peritoneum, tunica vaginalis testis and tunica serosa uteri. It is a dynamic structure important for tissue homeostasis by regulating inflammation and wound healing. Defects of the pleura are involved in the pathogenesis of pleural fibrosis and adhesions, and in malignant mesothelioma, an aggressive cancer associated with previous exposure to asbestos.

Currently, there is an inadequate understanding of pleural biology in health, which impedes the development of treatments for these pleural pathologies. To address this, we aimed to establish a reproducible protocol for the isolation and culture of mesothelial cells from human pleural tissue. Moreover, using single-cell RNA profiling, we explored the cellular heterogeneity of human pleura in 8 patients treated for pneumothorax (figure 1). This resulted in the generation of a comprehensive atlas composed of mesothelial, stromal and immune cells, providing a valuable resource for further pleural research.

**Abstract S98 Figure 1** Human parietal pleura scRNAseq of freshly prepared cells. T-distributed stochastic neighbour embedding (tSNE) of jointly analysed single-cell transcriptomes from 12,162 cells from 2 pneumothorax patients. **FLUORESCENCE-LIFETIME IMAGING: A NOVEL DIAGNOSTIC TOOL FOR SUSPECTED LUNG CANCER**

1. SE Rendres, GOS Williams, E Williams, N Finlayson, Q Wang, DA Dorward, C Dhalwal, WA Wallace, AR Akram, K Dhalwal. Translational Healthcare Technologies Group, Centre for Inflammation Research, Queen’s Medical Research Institute, The University of Edinburgh, Edinburgh, UK; 2Institute for Integrated Micro and Nano Systems, The University of Edinburgh, Edinburgh, UK; 3Department of Pathology, Royal Infirmary of Edinburgh, Edinburgh, UK; 4Department of Pathology, Western General Hospital, Edinburgh, UK.

**Introduction and Objectives** Lung cancer is the most common cause of cancer-related deaths. Early detection improves outcomes, however, the diagnostic yield of existing sampling techniques is suboptimal. Fluorescence-lifetime imaging microscopy (FLIM), an autofluorescence-based technique which measures endogenous fluorophore decay rates, may aid identification of optimal biopsy sites in suspected lung cancer. We describe the
